

DL: Practical

FCNN, CNNs, Keras, etc.

<https://www.manning.com/books/deep-learning-with-python>

Tensors & Tensor operations

- Tensors:
 - Scalars (0D tensors)
 - Vectors (1D tensors)
 - Matrices (2D tensors): (samples, features)
 - 3D tensors: Timeseries: (samples, timesteps, features)
 - Higher-dimensional tensors:
 - Images: (samples, height, width, channels)
 - Video: (samples, frames, height, width, channels)
- Key attributes
 - Number of axes (rank): `>>> print(train_images.ndim) -> 3`
 - Shape: `>>> print(train_images.shape) -> (60000, 28, 28)`
 - Data type: `print(train_images.dtype) -> uint8`

Keras

<https://keras.io>

- Keras workflow:
 - Define your training **data**: input tensors and target tensors.
 - Define a network of layers (or **model**) that maps your inputs to your targets.
 - **Configure** the learning process by choosing a loss function, an optimizer, and some metrics to monitor.
 - Iterate on your training data by calling the **fit()** method of your model.
 - evaluate / predict (testing / new unseen data)

Figure 3.2. Google web search interest for different deep-learning frameworks over time

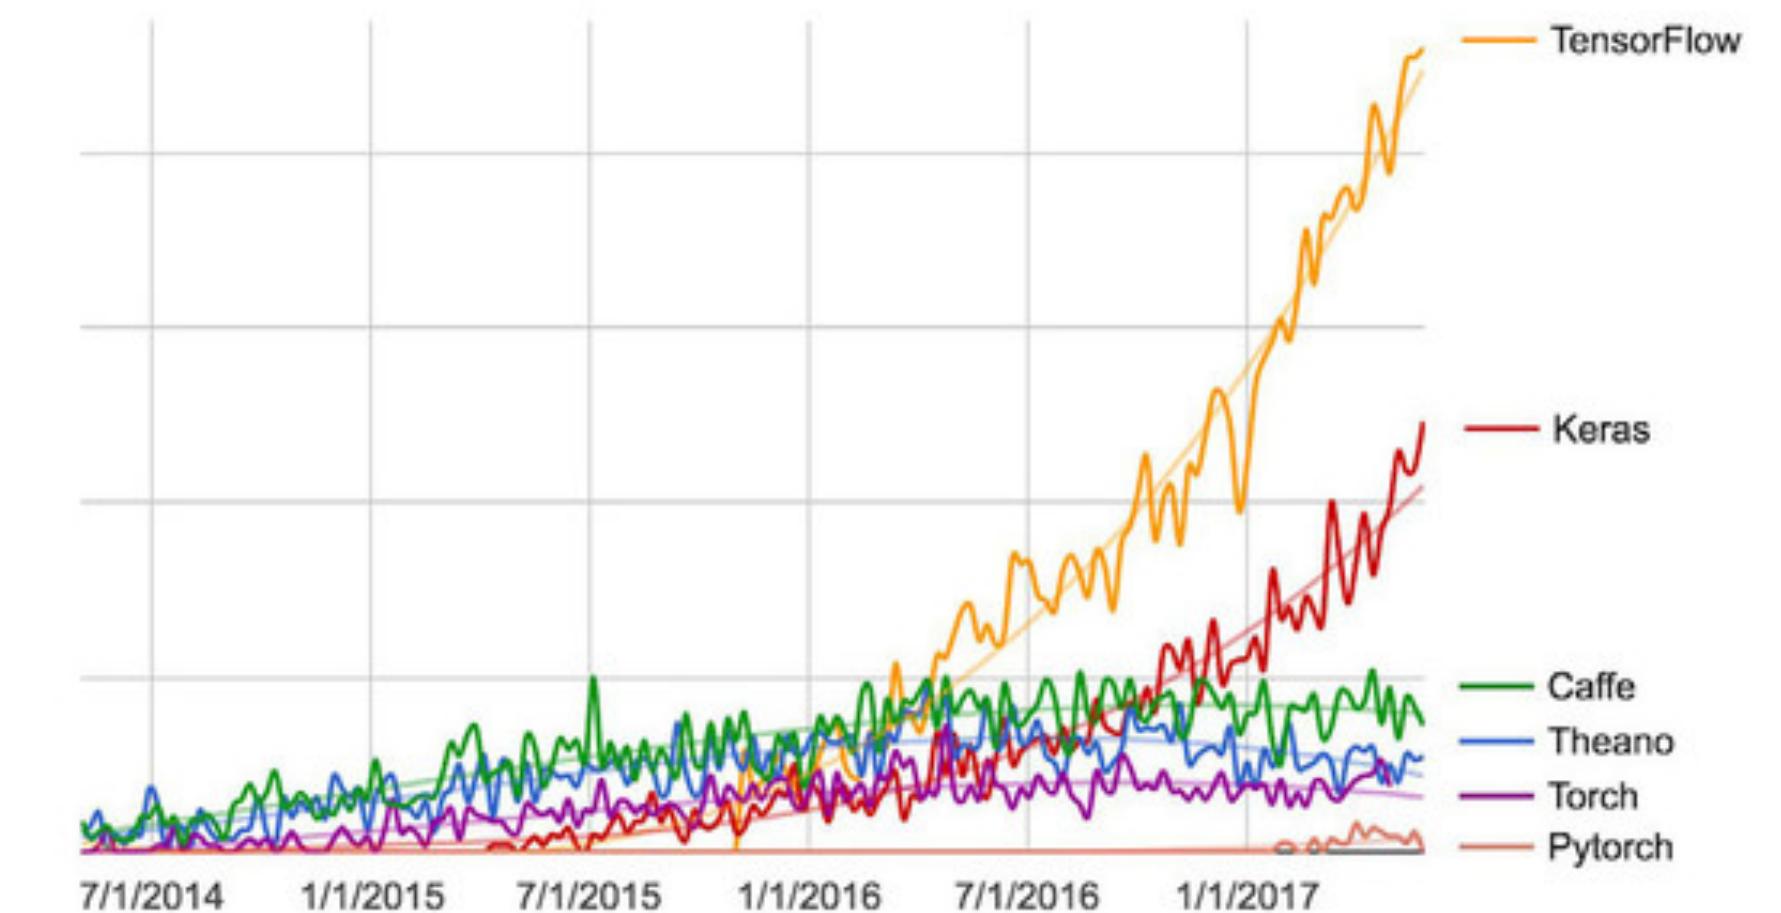

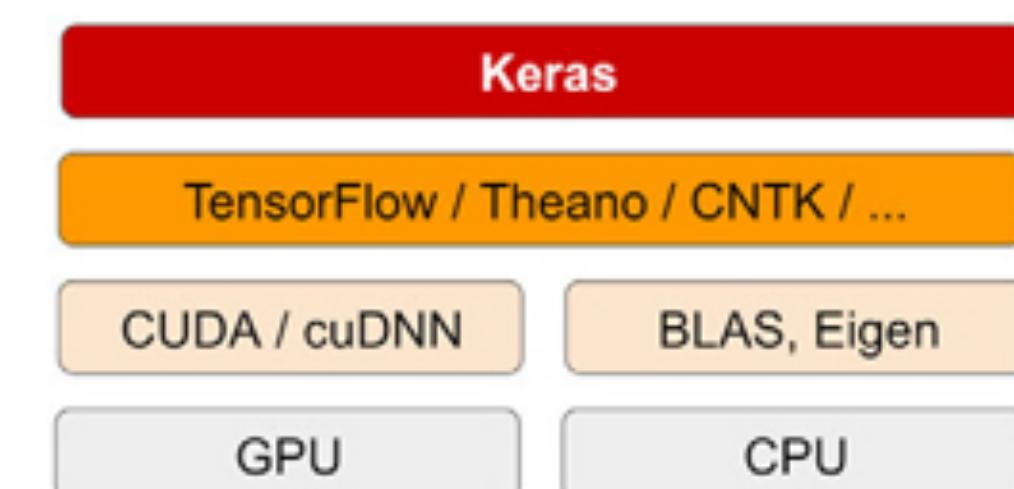

Figure 3.3. The deep-learning software and hardware stack

Intro to dense NNs & Keras

Figure 2.1. MNIST sample digits

- “Hello World” of DL: “solving” MNIST
- MNIST dataset comes preloaded in Keras
(Numpy arrays)
 - training set: train_images and train_labels
 - test set: test_images and test_labels

Listing 2.1. Loading the MNIST dataset in Keras

```
1 from keras.datasets import mnist
2 (train_images, train_labels), (test_images, test_labels) = mnist.load_data()

1 >>> train_images.shape
2 (60000, 28, 28)
3 >>> len(train_labels)
4 60000
5 >>> train_labels
6 array([5, 0, 4, ..., 5, 6, 8], dtype=uint8)

1 >>> test_images.shape
2 (10000, 28, 28)
3 >>> len(test_labels)
4 10000
5 >>> test_labels
6 array([7, 2, 1, ..., 4, 5, 6], dtype=uint8)
```

Intro to dense NNs & Keras (2)

- Build the network: layers (lego):
 - densely connected = fully connected layers
 - «**compile**» = make the network ready for training
- Preprocess the data:
 - labels: one-hot encoding / categorical encoding
- Workflow:
 - Feed the training data to the NN which will learn to **associate** images and labels
 - Produce **predictions** for test_images, and verify whether these predictions **match** the labels from test_labels

Listing 2.2. The network architecture

```
1 from keras import models
2 from keras import layers
3
4 network = models.Sequential()
5 network.add(layers.Dense(512, activation='relu', input_shape=(28 * 28,)))
6 network.add(layers.Dense(10, activation='softmax'))
```

Listing 2.3. The compilation step

```
1 network.compile(optimizer='rmsprop',
2                   loss='categorical_crossentropy',
3                   metrics=['accuracy'])
```

Listing 2.4. Preparing the image data

```
1 train_images = train_images.reshape((60000, 28 * 28))
2 train_images = train_images.astype('float32') / 255
3
4 test_images = test_images.reshape((10000, 28 * 28))
5 test_images = test_images.astype('float32') / 255
```

Listing 2.5. Preparing the labels

```
1 from keras.utils import to_categorical
2
3 train_labels = to_categorical(train_labels)
4 test_labels = to_categorical(test_labels)
```

Intro to dense NNs & Keras (3)

- «**fit**»: train the network

- loss and accuracy

- Training accuracy: 98.9%

```
1 >>> network.fit(train_images, train_labels, epochs=5, batch_size=128)
2 Epoch 1/5
3 60000/60000 [=====] - 9s - loss: 0.2524 - acc: 0.9273
4 Epoch 2/5
5 51328/60000 [=====>.....] - ETA: 1s - loss: 0.1035 - acc: 0.9
```

- «**evaluate**»: check that the model performs well on the unsent test set

- Test accuracy: 97.8%

- gap is an indication of overfitting

```
1 >>> test_loss, test_acc = network.evaluate(test_images, test_labels)
2
3 >>> print('test_acc:', test_acc)
test_acc: 0.9785
```

- «**predict**»:

- >>> model.predict(x_test)

Intro to dense NNs & Keras (4)

Another dataset, not MNIST

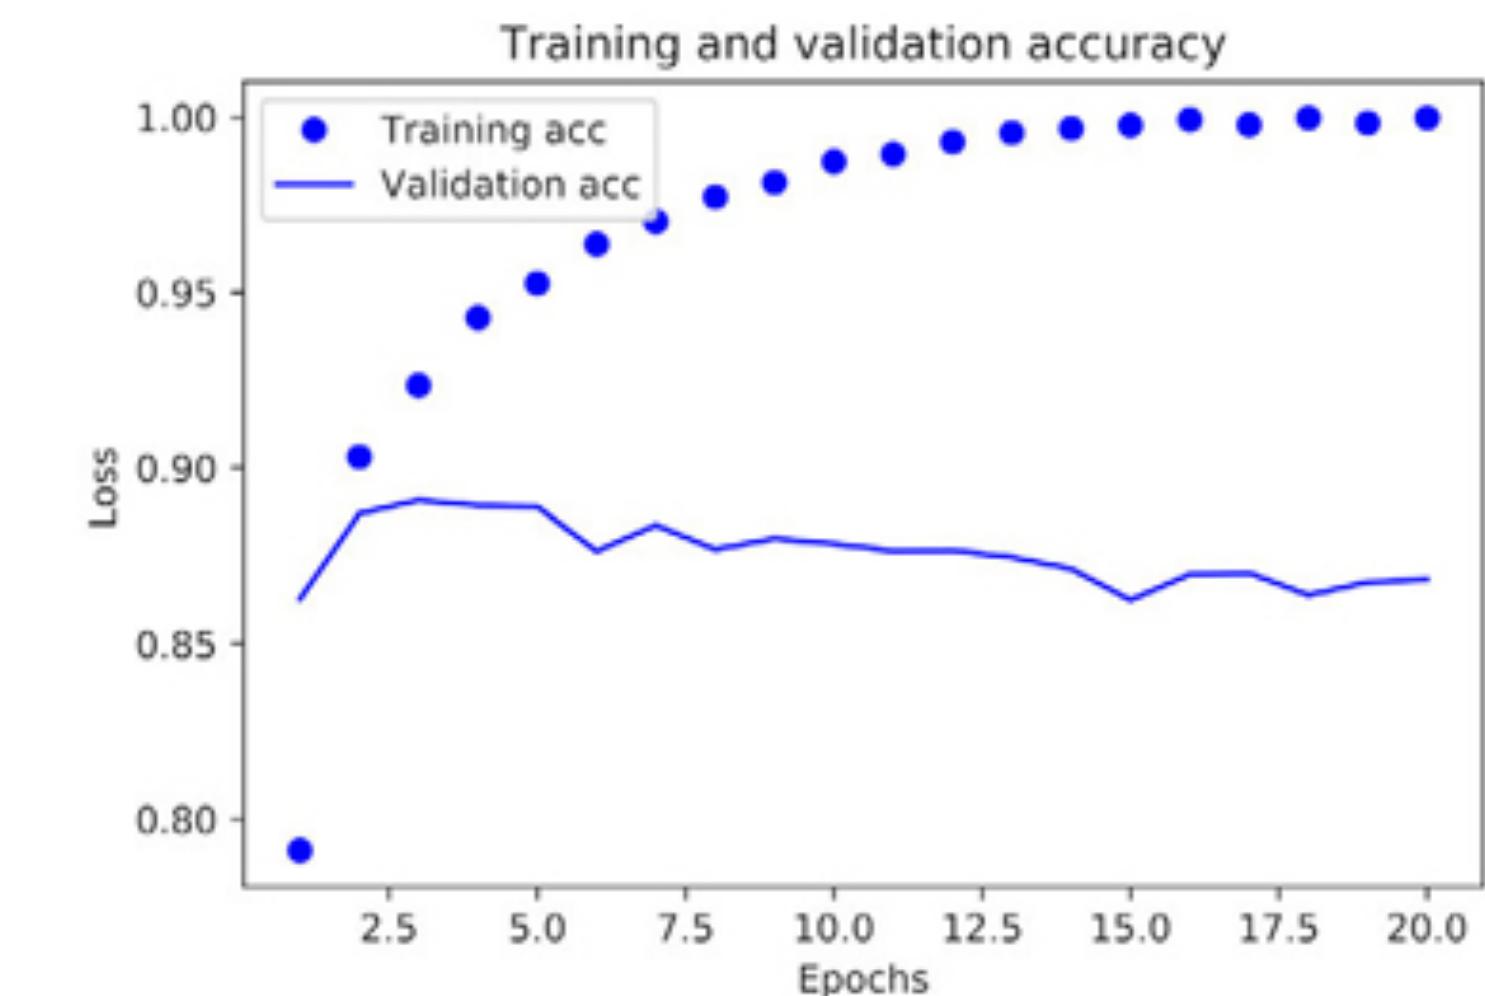

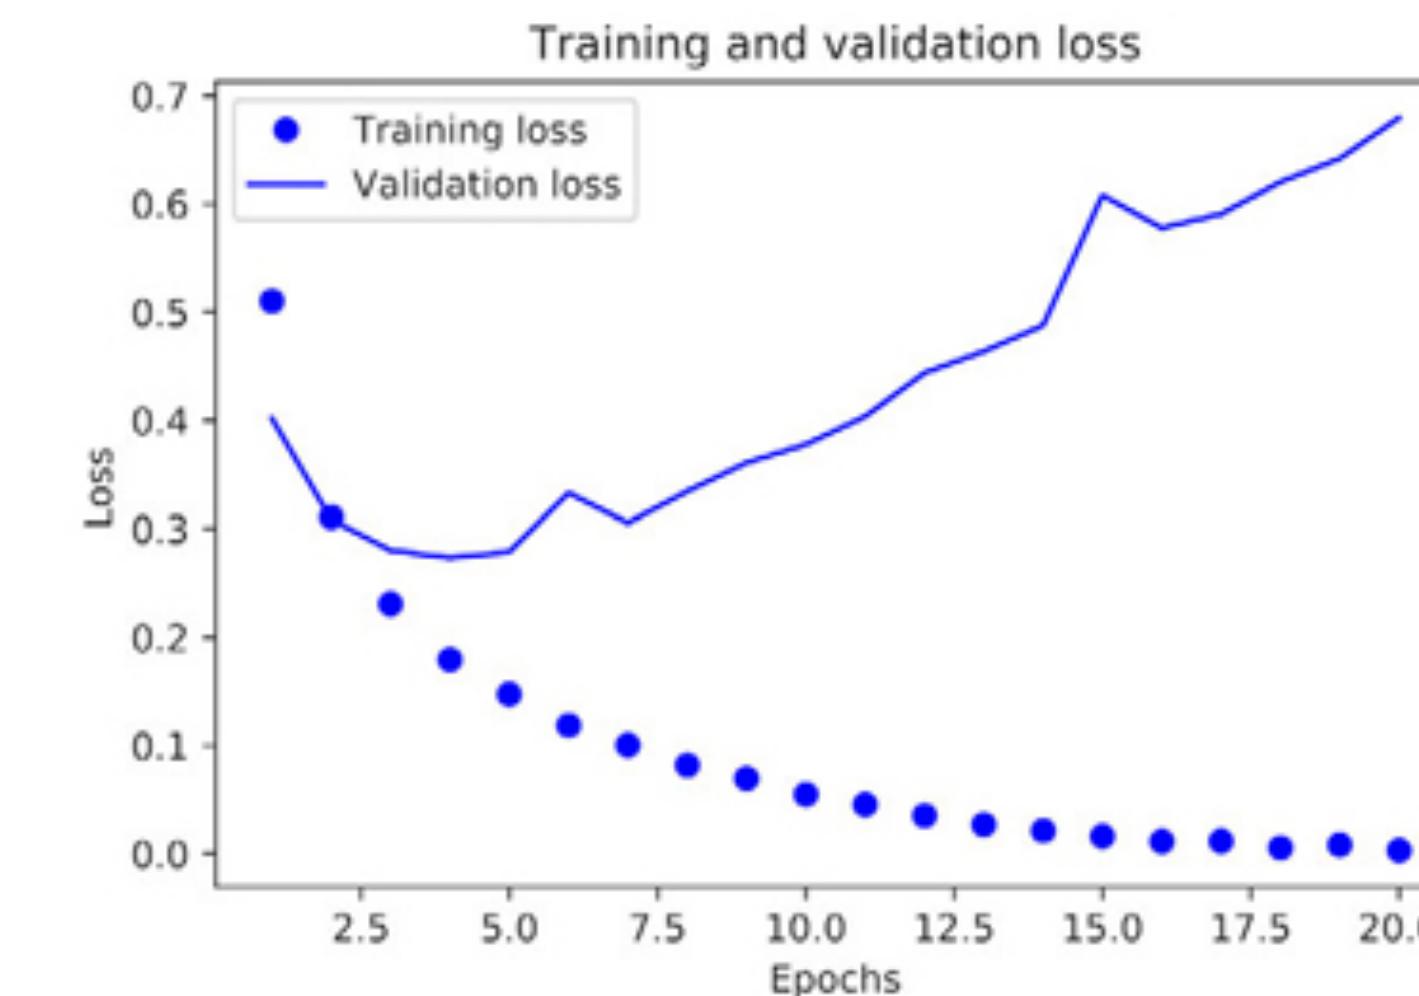

Listing 3.7. Setting aside a validation set

```
1 x_val = x_train[:10000]
2 partial_x_train = x_train[10000:]
3 y_val = y_train[:10000]
4 partial_y_train = y_train[10000:]
```

- Validation:
 - create a validation set by setting some of the samples from the original training data
 - monitor during training the accuracy of the model on data it has never seen before

Listing 3.8. Training your model

```
1 model.compile(optimizer='rmsprop',
2                 loss='binary_crossentropy',
3                 metrics=['acc'])
4
5 history = model.fit(partial_x_train,
6                      partial_y_train,
7                      epochs=20,
8                      batch_size=512,
9                      validation_data=(x_val, y_val))
```

Summary: Chap 2

- **Learning** means finding a *combination* of model parameters that *minimizes* a loss function for a given set of training data samples and their corresponding targets.
- Learning happens by drawing random **batches** of data samples and their targets, and computing the **gradient** of the network parameters with respect to the **loss** on the batch. The network parameters are then moved a bit (the magnitude of the move is defined by the **learning rate**) in the opposite direction from the gradient.
- The entire learning process is made possible by the fact that neural networks are **chains of differentiable tensor operations**, and thus it's possible to apply the **chain rule** of derivation to find the gradient function mapping the current parameters and current batch of data to a gradient value.
- Two key concepts you'll see frequently in future chapters are **loss** and **optimizers**. These are the two things you need to define before you begin feeding data into a network.
- The **loss** is the quantity you'll attempt to **minimize** during training, so it should represent a measure of **success** for the task you're trying to solve.
- The **optimizer** specifies the exact way in which the **gradient** of the loss will be used to **update** parameters: for instance, it could be the RMSProp optimizer, **SGD** with momentum, and so on.

Summary: Chap 3

- You're now able to handle the most **common** kinds of machine-learning tasks on **vector data**: binary classification, multi-class classification, and scalar regression. The “**Wrapping up**” sections earlier in the chapter summarize the important points you've learned regarding these types of tasks.
- You'll usually need to **preprocess** raw data before feeding it into a neural network.
- When your data has features with **different ranges**, **scale** each feature independently as part of preprocessing.
- As training progresses, neural networks eventually begin to **overfit** and obtain worse results on never-before-seen data.
- If you don't have much training data, use a **small network** with only one or two hidden layers, to avoid severe overfitting.
- If your data is divided into many categories, you may cause information bottlenecks if you make the intermediate layers too small.
- **Regression** uses different loss functions and different evaluation metrics than classification.
- When you're working with little data, K-fold validation can help reliably evaluate your model.

5.1. Introduction to convnets

Listing 5.1. Instantiating a small convnet

```
1 from keras import layers  
2 from keras import models  
3  
4 model = models.Sequential()  
5 model.add(layers.Conv2D(32, (3, 3), activation='relu', input_shape=(28, 28, 1)))  
6 model.add(layers.MaxPooling2D((2, 2)))  
7 model.add(layers.Conv2D(64, (3, 3), activation='relu'))  
8 model.add(layers.MaxPooling2D((2, 2)))  
9 model.add(layers.Conv2D(64, (3, 3), activation='relu'))
```

- `input_shape=(28, 28, 1)`
- `(image_height, image_width, image_channels)`

5.1. Introduction to convnets (2)

$$(3 \times 3 \times 1) \times 32 + 32 = 9 \times 32 + 32 = 288 + 32 = 320$$

$$(3 \times 3 \times 32) \times 64 + 64 = 288 \times 64 + 64 = 18432 + 64 = 18496$$

```

16                 metrics=['accuracy'])
17 model.fit(train_images, train_labels, epochs=5, batch_size=64)
```

- Train the convnet on the MNIST digits
- astype
- to_categorical

5.1. Introduction to convnets (6)

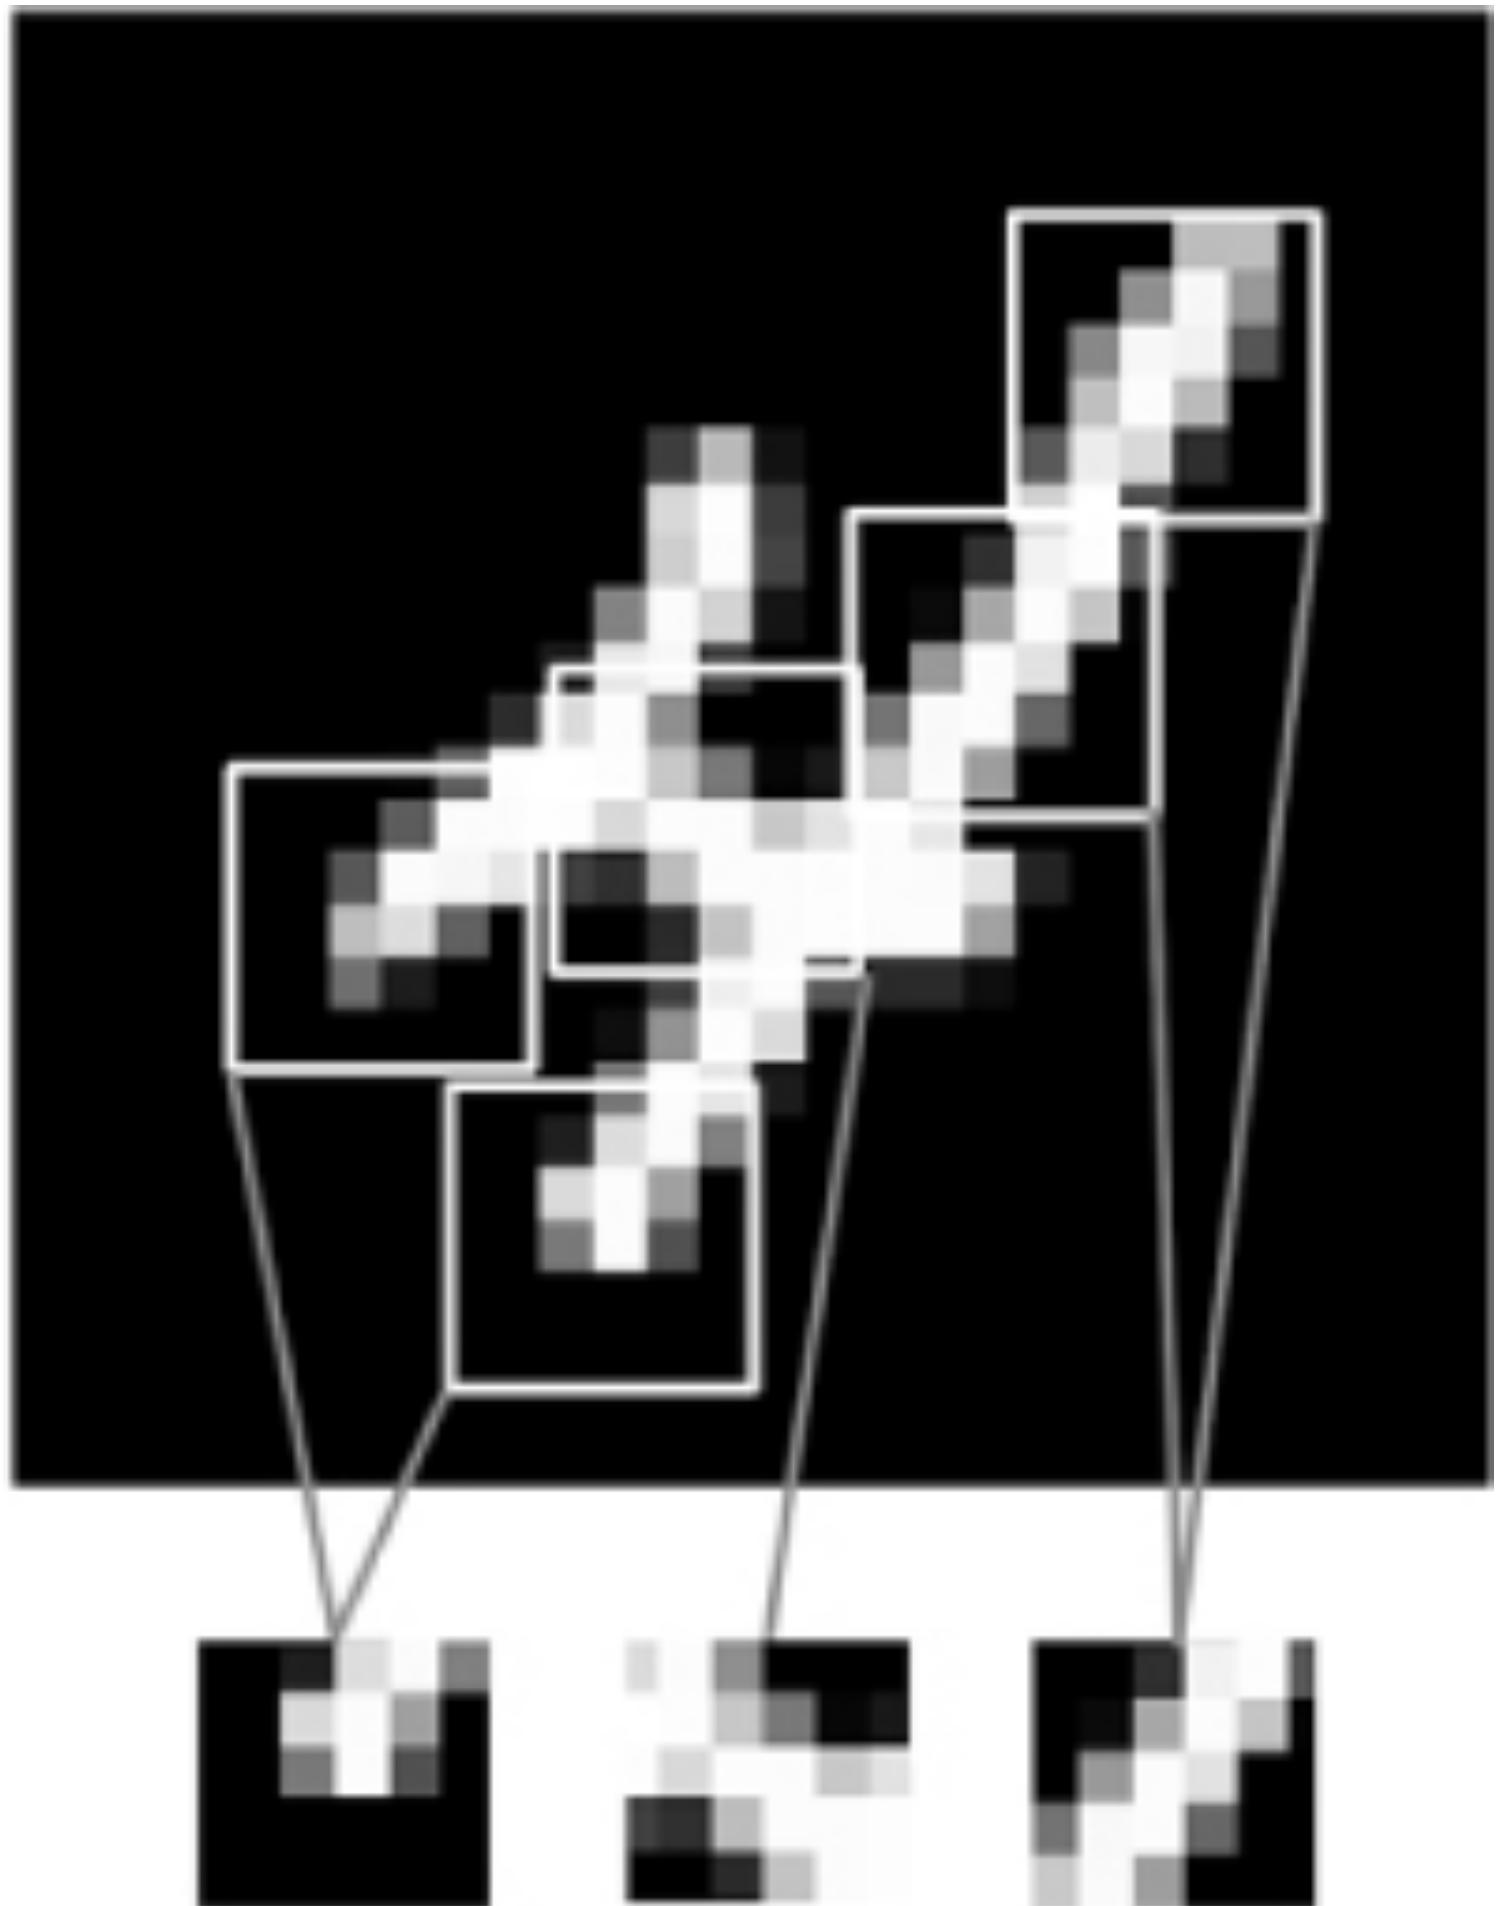

```
1 >>> test_loss, test_acc = model.evaluate(test_images, test_labels)
2 >>> test_acc
3 0.9908000000000001
```

- Evaluate the model
- From 97.8% (FC/Dense) to 99.1% (simple CNN), error rate down by 68%
- Why?

5.1.1. The convolution operation

- Fundamental difference
 - Dense layer: **global** patterns (all pixels)
 - Convolution layer: **local** patterns (small 2D windows)

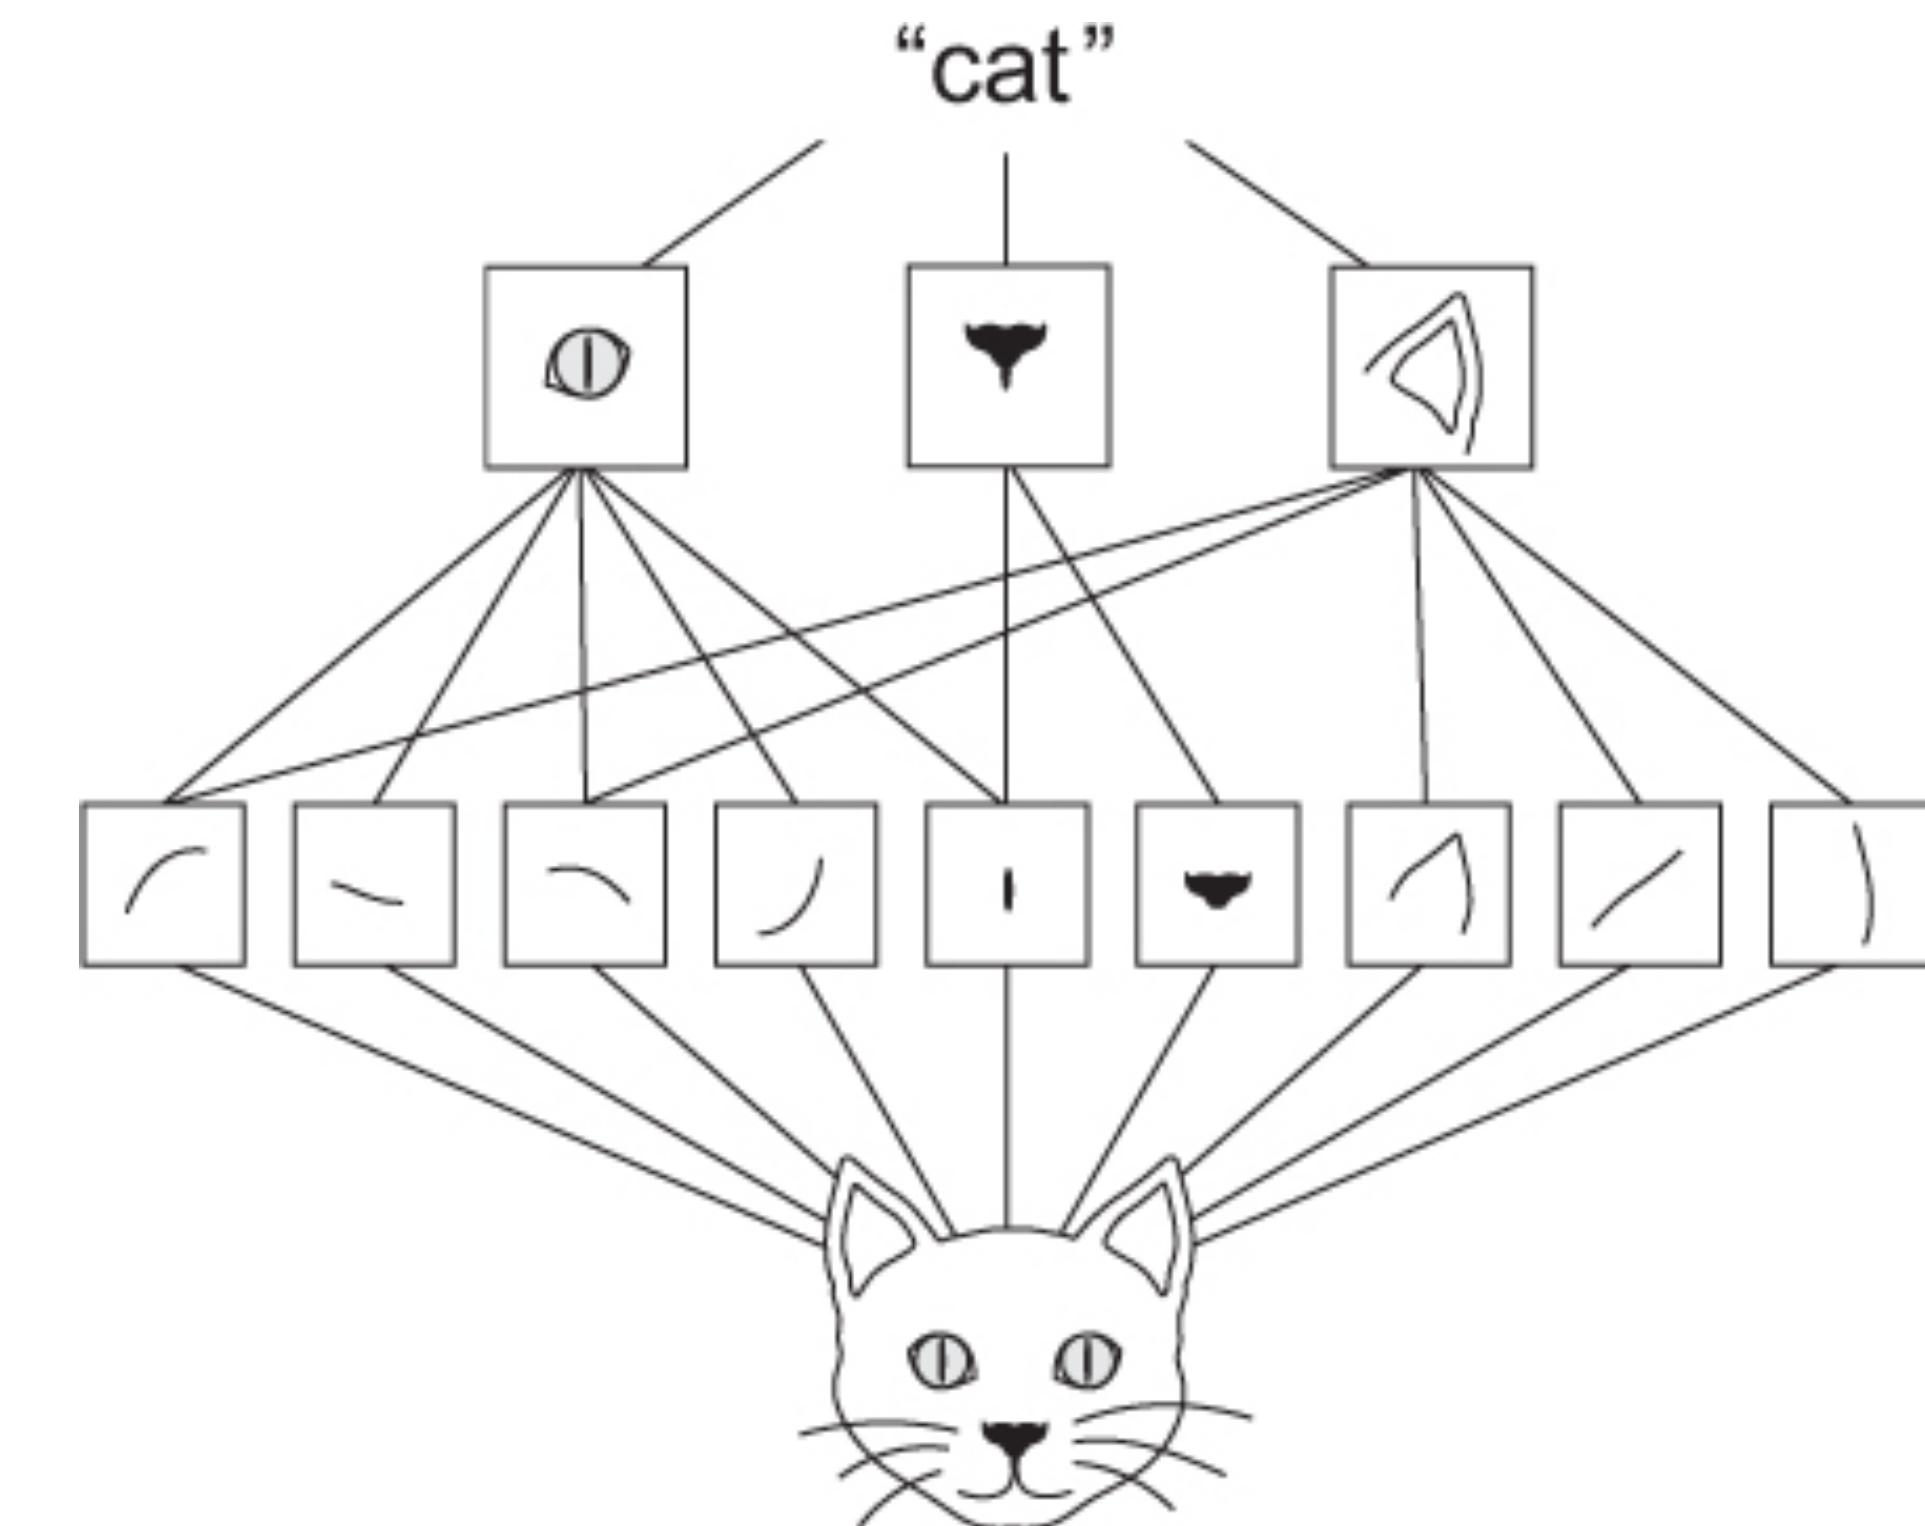

Figure 5.1. Images can be broken into **local** patterns such as edges, textures, and so on.

5.1.1. The convolution operation (2)

- Key characteristics / properties of convnets:
 - The patterns they learn are **translation invariant** (patterns learned are recognized anywhere, visual world is trans. inv.)
 - They can learn **spatial hierarchies** of patterns (1: learn small local patterns such as edges, 2: learn larger patterns made of the features of the first layers, 3: and so on, i.e. learn increasingly complex and abstract visual concepts)
 - The **visual world** is fundamentally **translation invariant & spatially hierarchical**

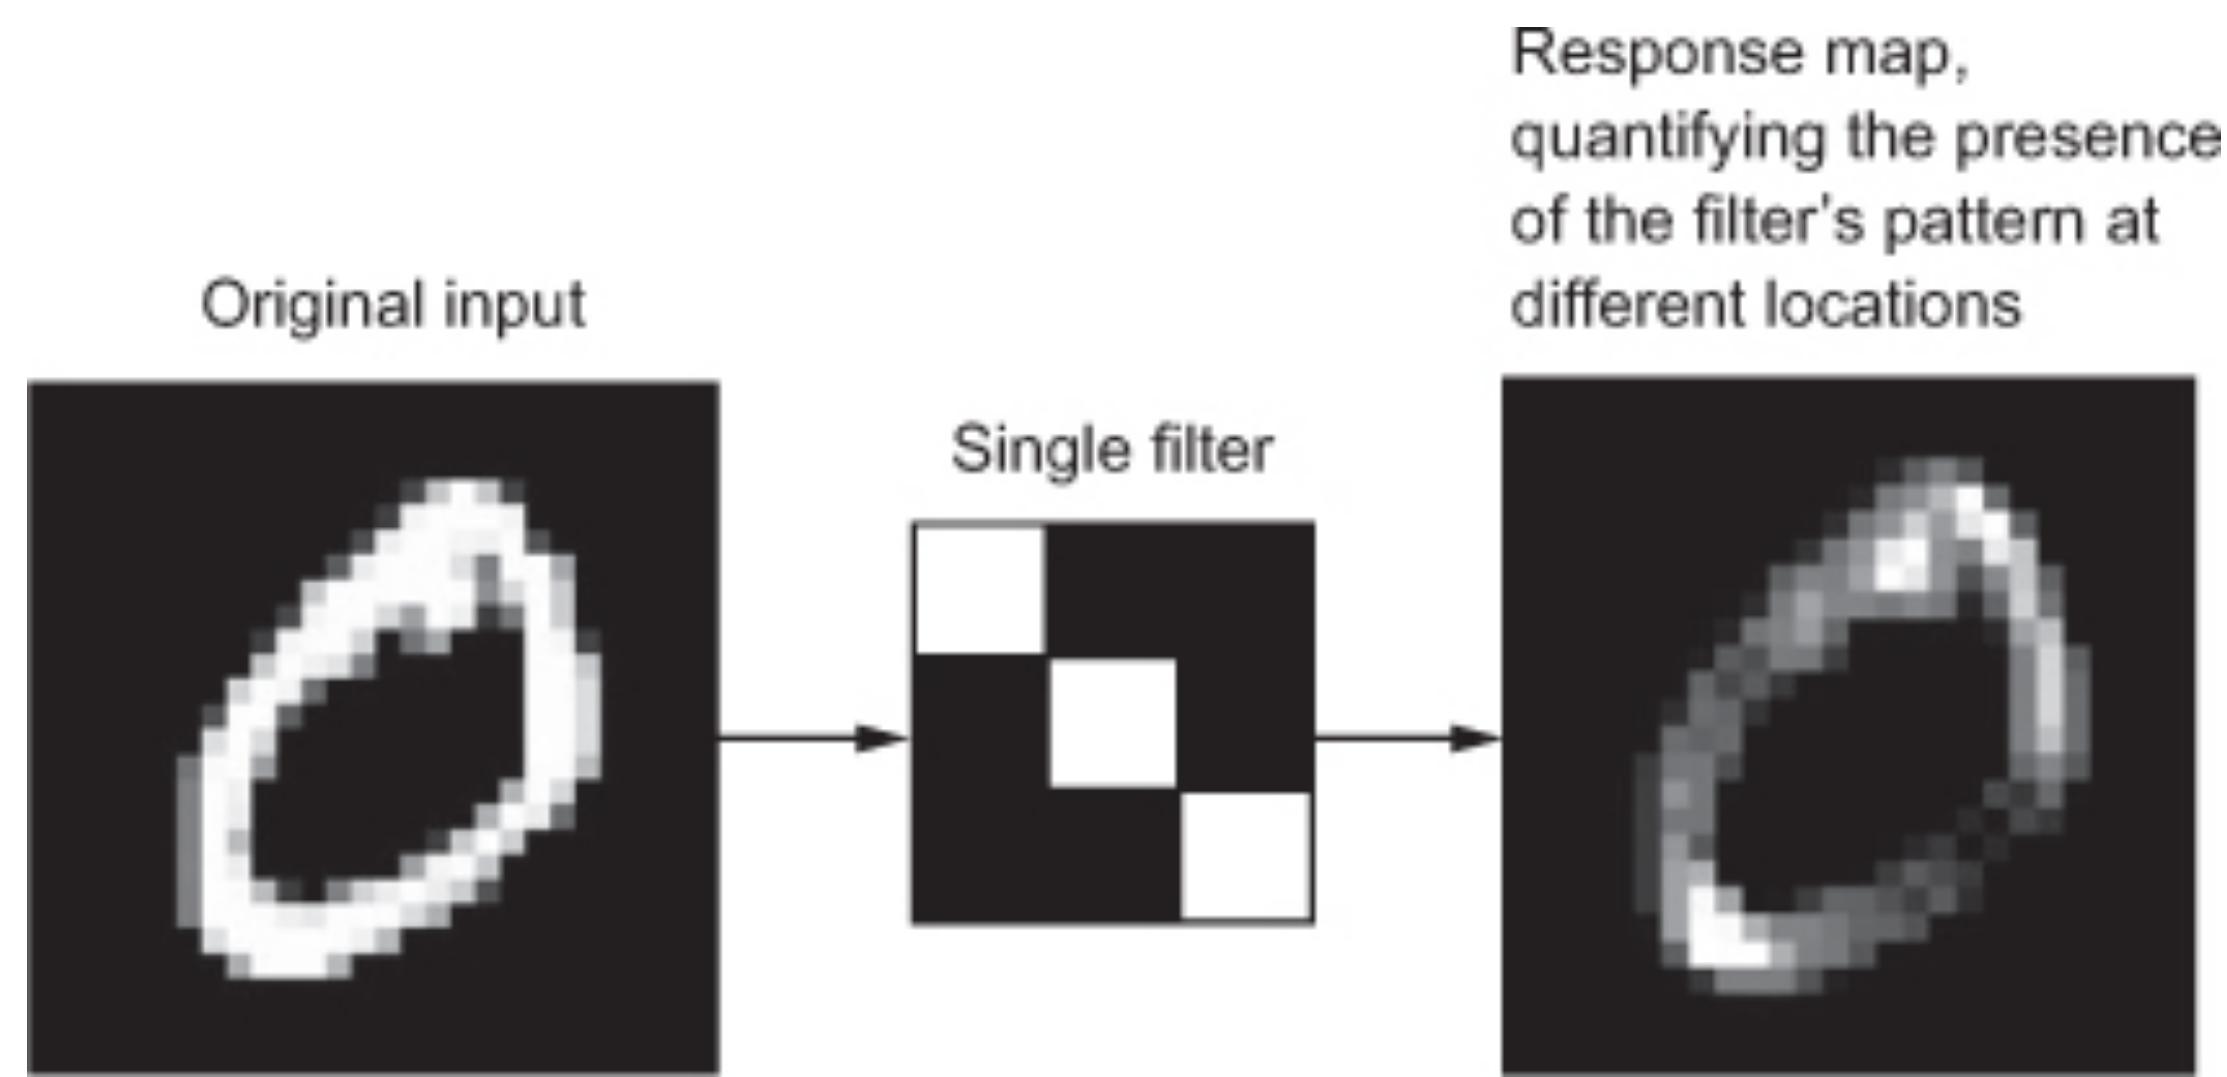

Figure 5.2. The visual world forms a **spatial hierarchy** of visual modules: **hyperlocal edges** combine into **local objects** such as eyes or ears, which combine into **high-level concepts** such as “cat.”

5.1.1. The convolution operation (3)

- Convolution operations (images): 3D input tensors / **feature maps** -> 3D output tensors / feature maps
 - height, width and depth / **channels** axis (e.g. RGB (3) or gray (1)).
 - extracts **patches** from input feature map, apply the same **transformation** to all of these patches, producing an output feature map.
 - the different channels in that depth axis stand for **filters** that encode specific aspects of the input data (high level: presence of a face)
 - MNIST: (28, 28, 1) -> (26, 26, 32), i.e. 32 filters / features, each a 2D spatial **response map**, i.e. the response of this filter over the input (patch by patch).

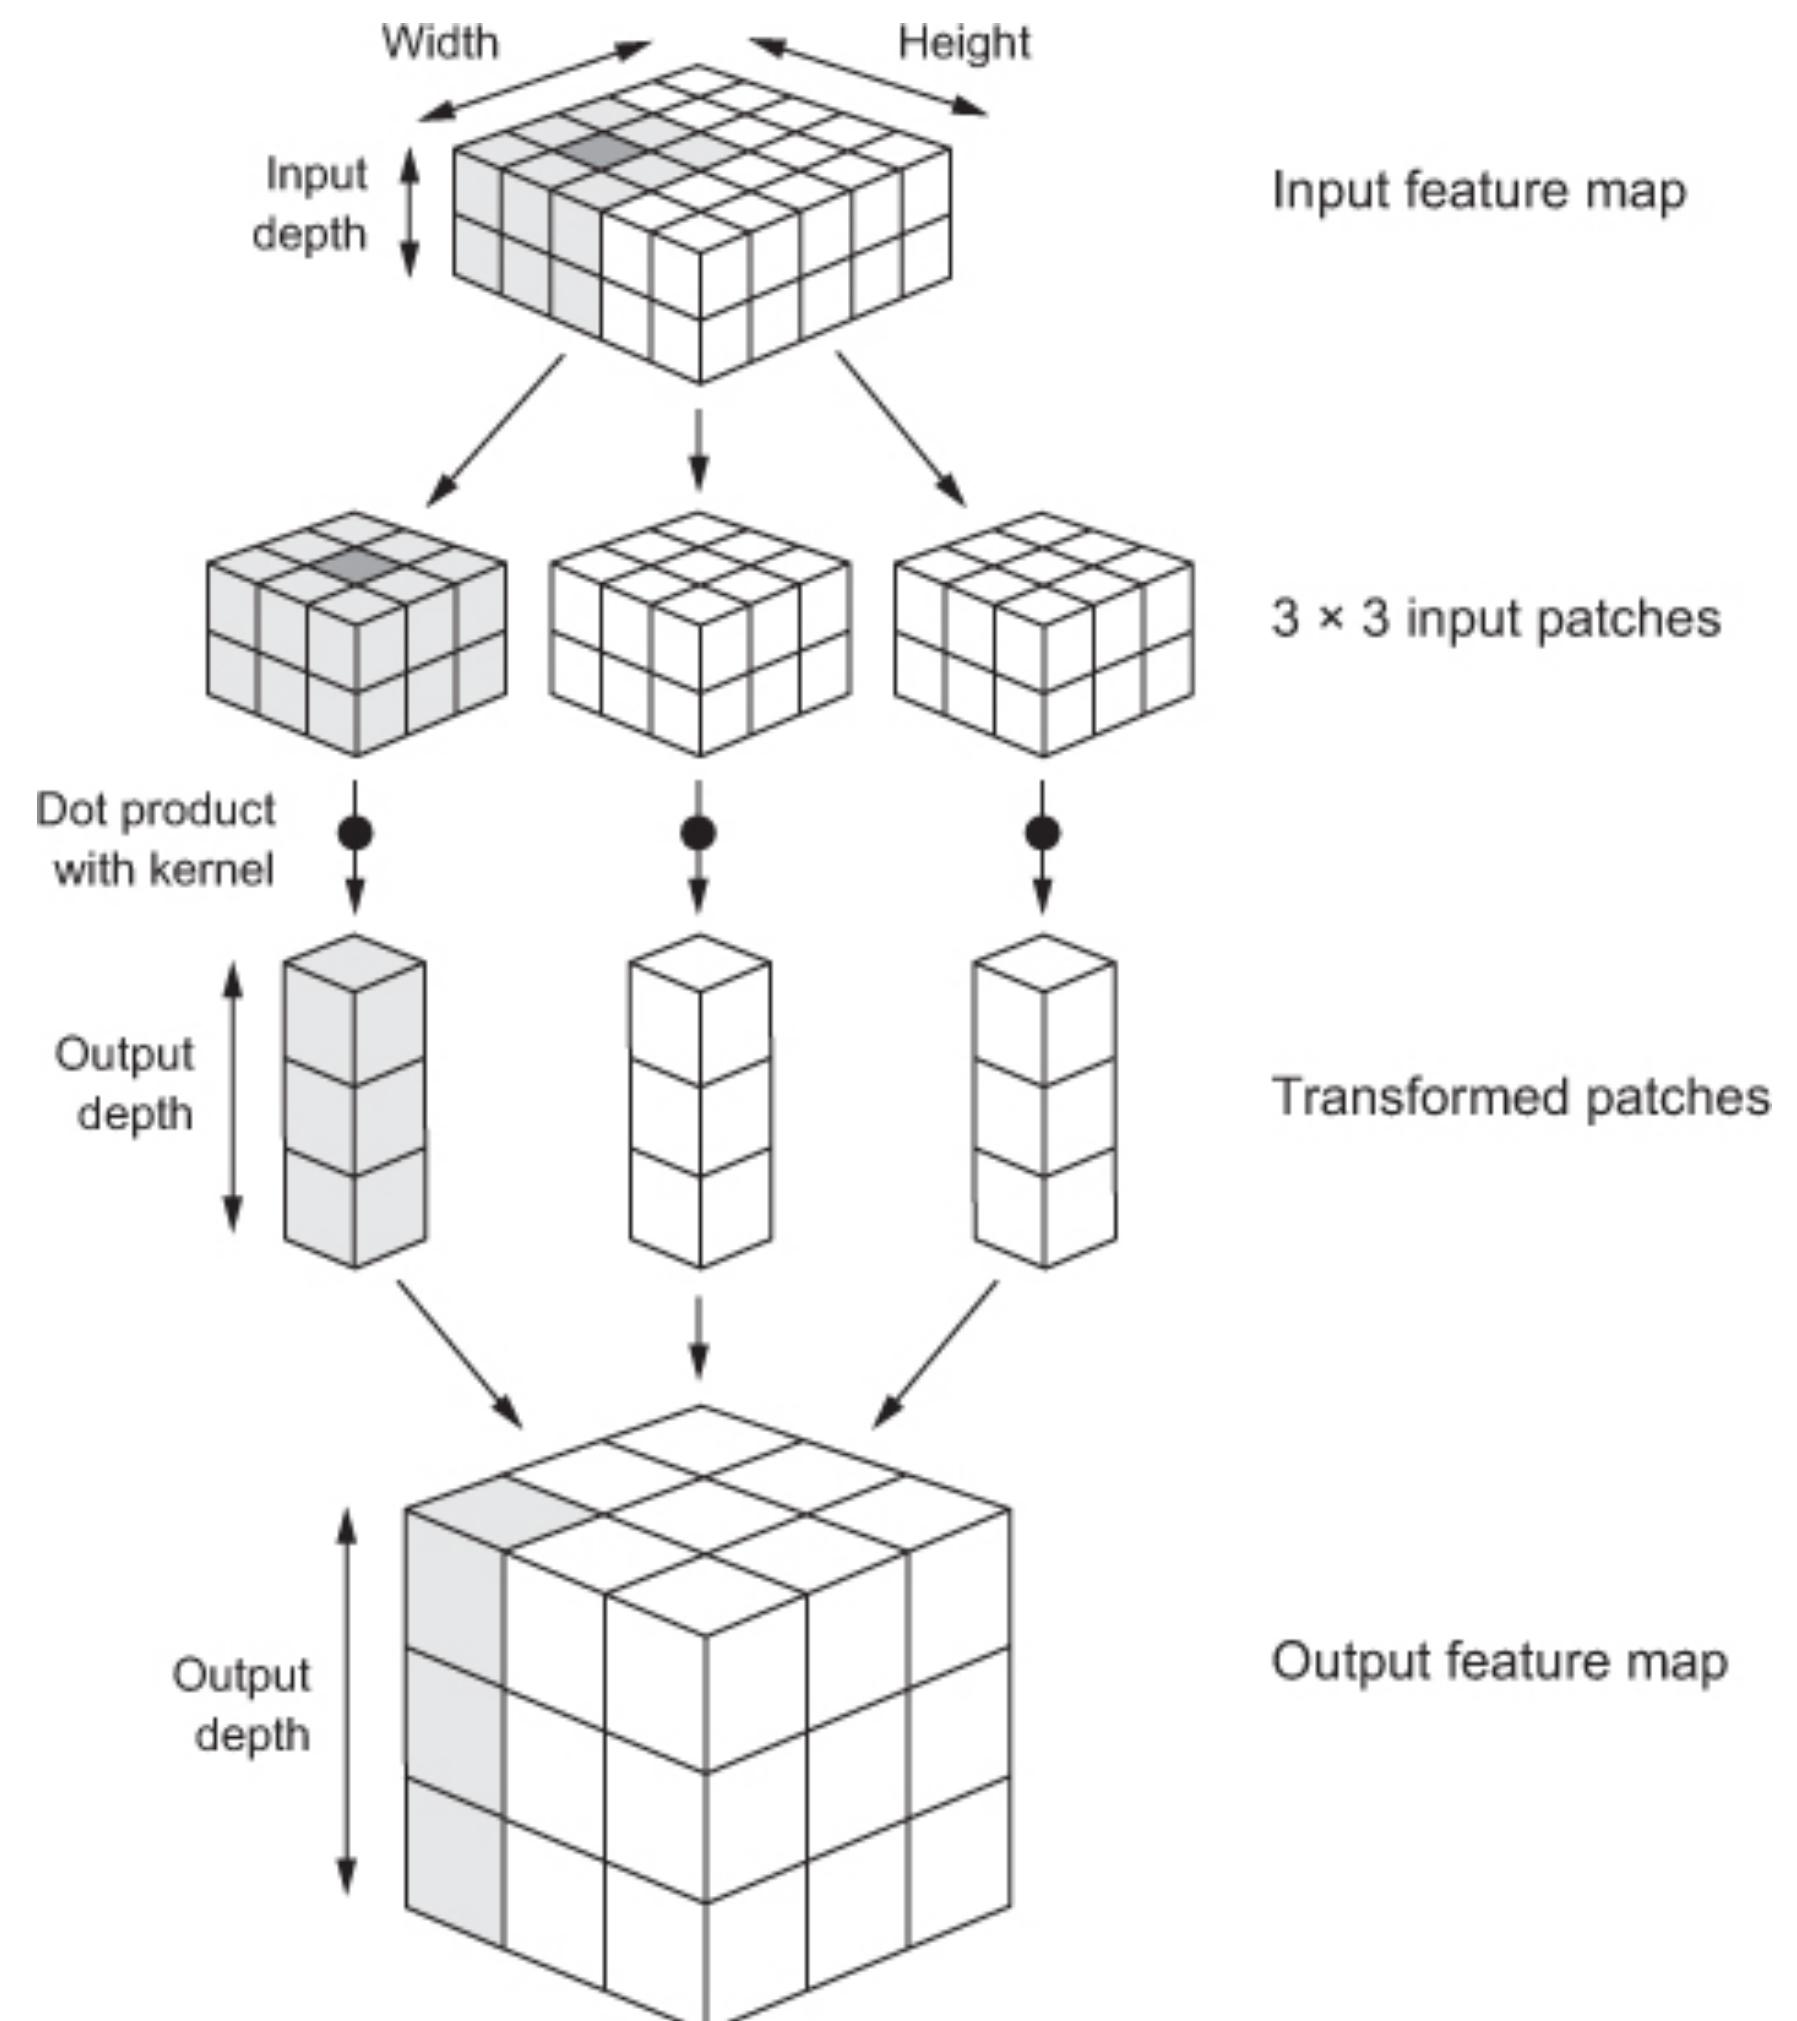

Figure 5.3. The concept of a **response map**: a 2D map of the **presence** of a **pattern** at different **locations** in an input

5.1.1. The convolution operation (4)

- Convolutions are defined by two key parameters:
 - **Size of the patches** extracted from the inputs (3×3 or 5×5)
 - **Depth** of the output feature map: **# filters** computed
- Works by sliding these windows (e.g. 3×3) over the 3D input feature map
 - extract a 3D patch of shape (window_height, window_width, input_depth).
 - transform via a tensor product with the same learned weight matrix, called the **convolution kernel**.
 - a new **product** for each filter / kernel, making a 1D vector of shape (output_depth,)
 - spatially reassemble into a 3D output map of shape (height, width, output_depth). Every spatial **location** in the output feature map corresponds to the same location in the input feature map
- output width and height may **differ** from the input width and height for two reasons: border effects (padding) & strides

Figure 5.4. How convolution works

5.1.1: Border effects and padding

- Consider a 5×5 feature map (25 tiles total):
 - can only center 9 3×3 windows forming a 3×3 grid so the output feature map will be 3×3 .
 - it shrinks by two tiles alongside each dimension (MNIST: 28×28 become 26×26)
- Use **padding** to get an output feature map with the same spatial dimensions as the input
 - add appropriate number of rows and columns to fit center convolution windows around every input tile
 - valid or same

Figure 5.5. Valid locations of 3×3 patches in a 5×5 input **feature map**

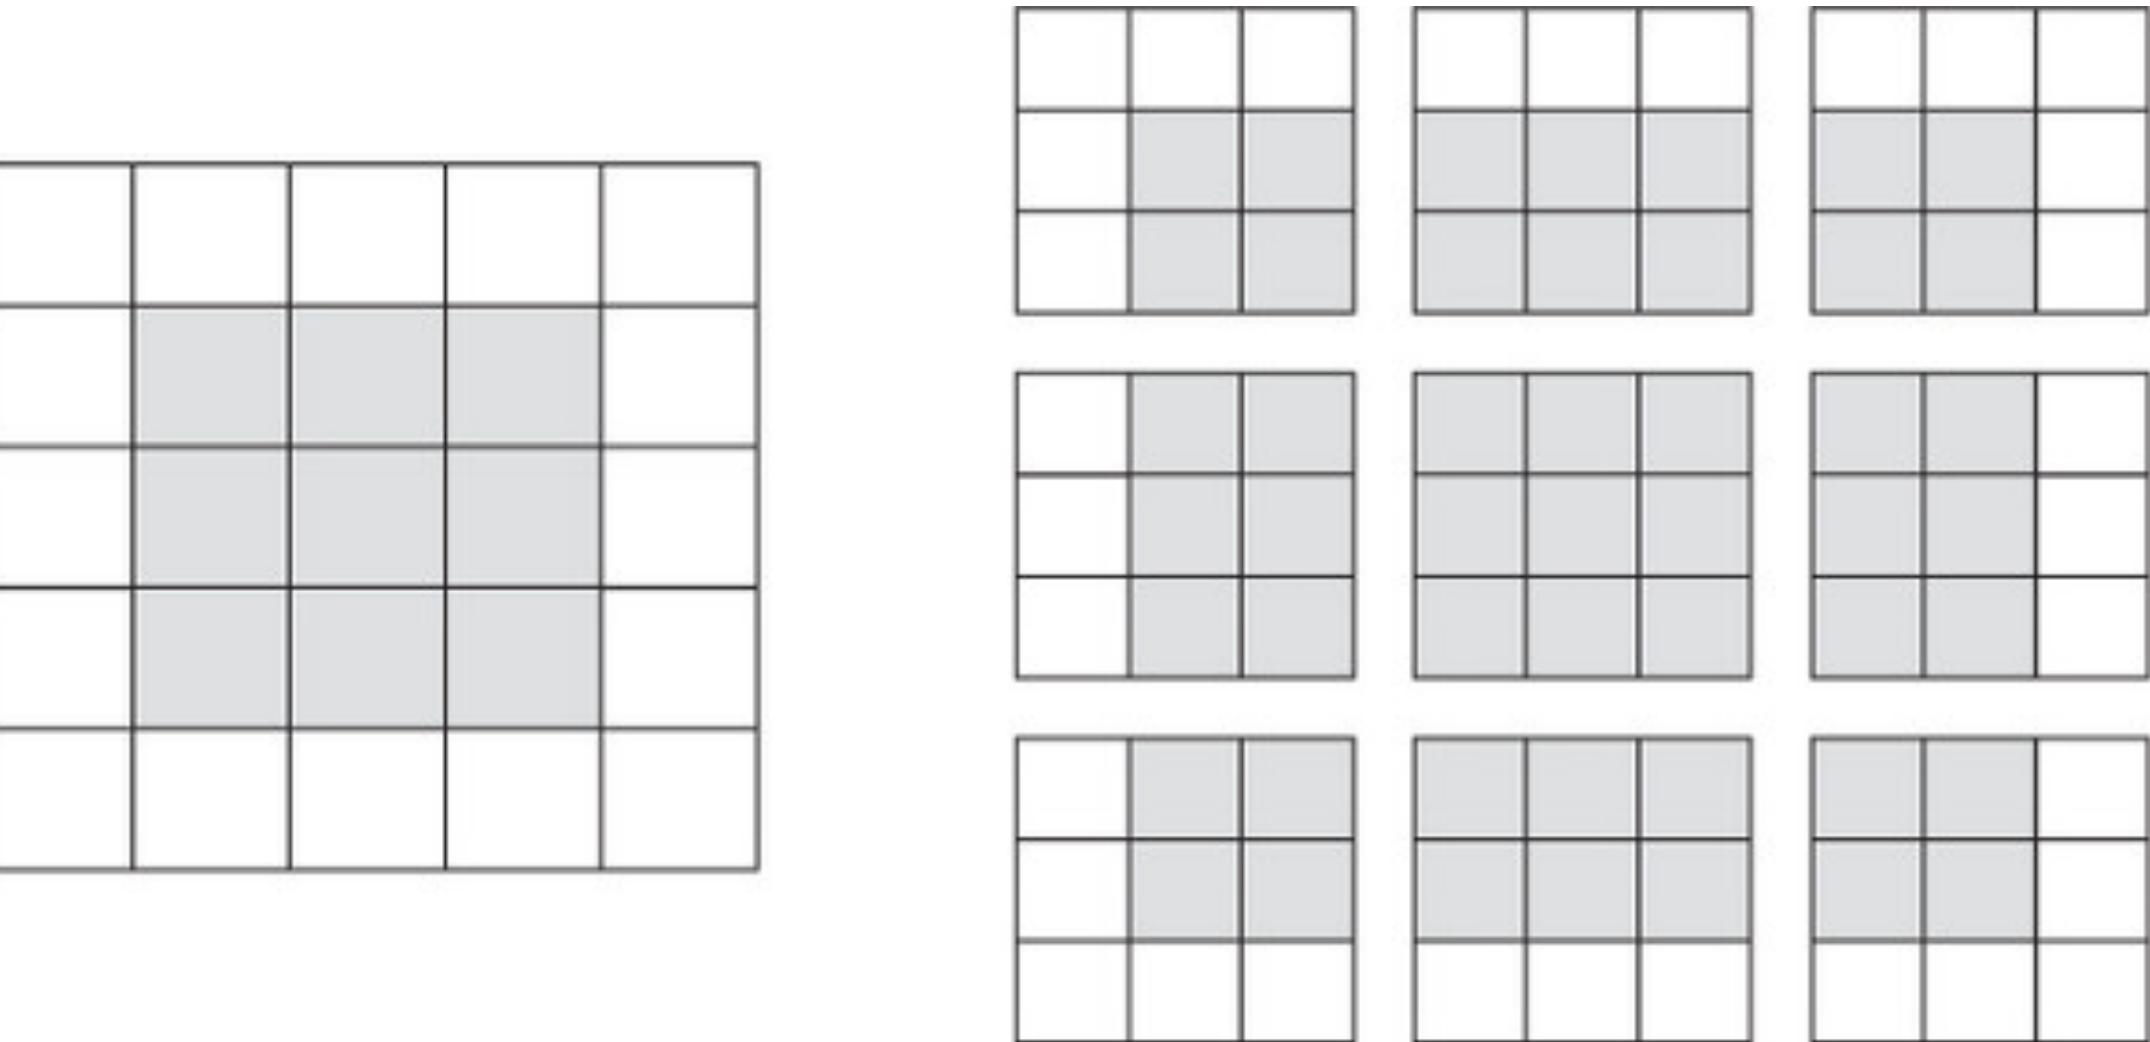

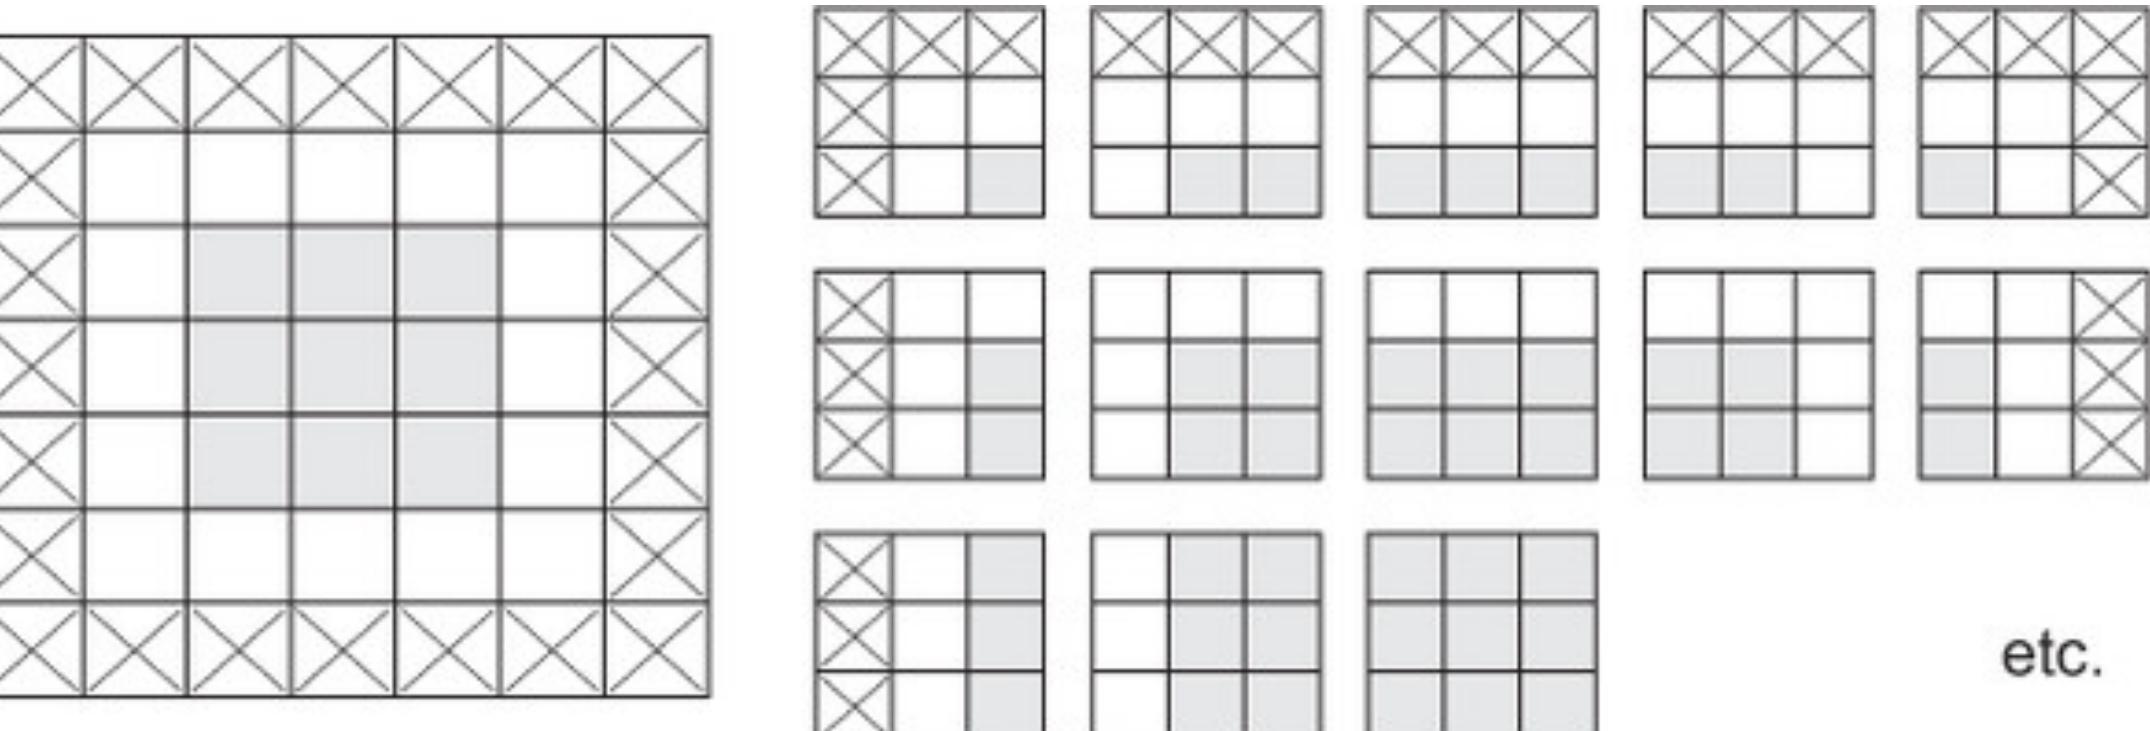

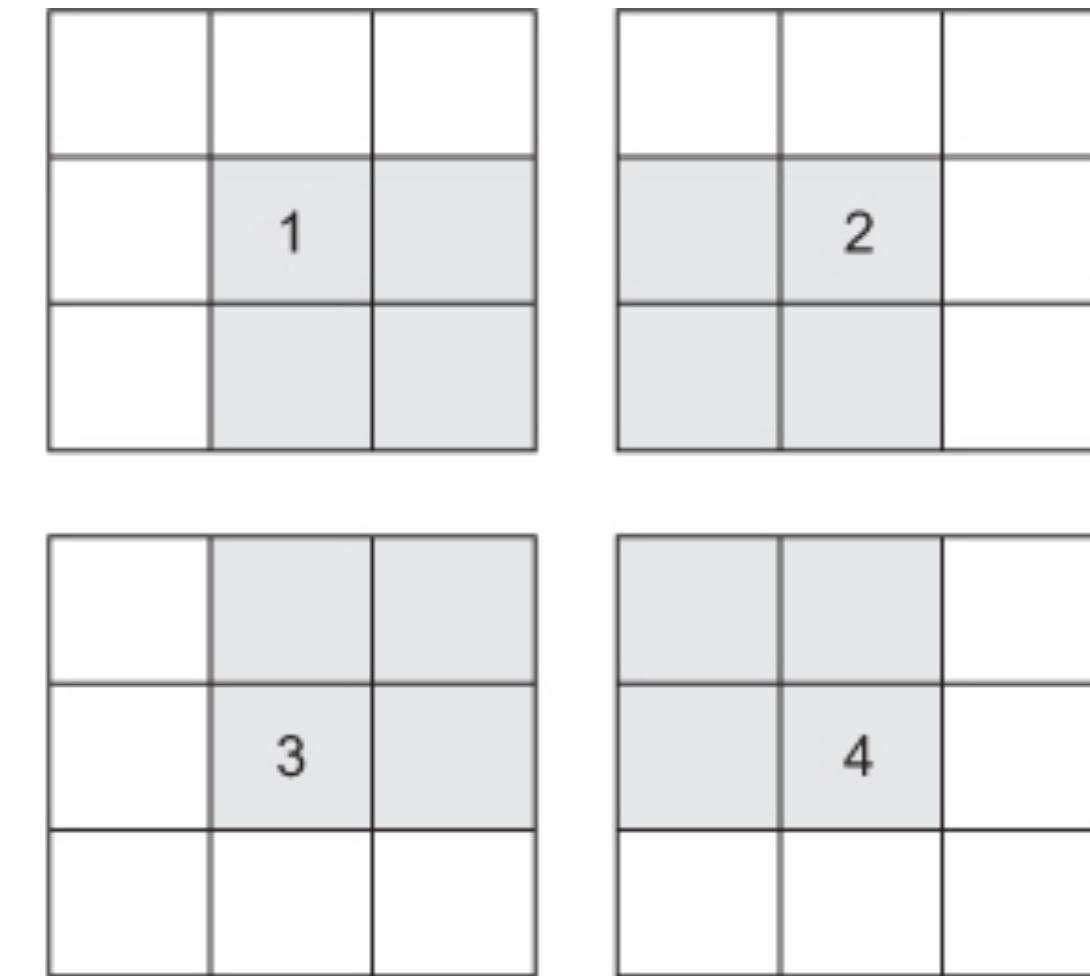

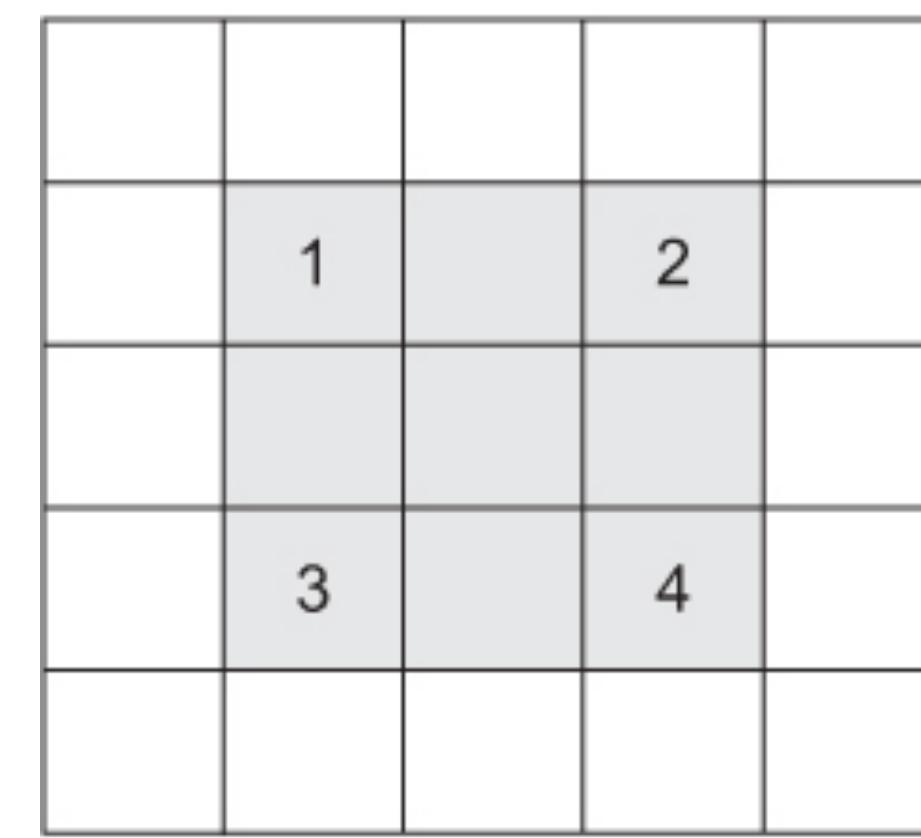

Figure 5.6. Padding a 5×5 input in order to be able to extract 25 3×3 patches

5.1.1: Strides

- **stride:** distance between two successive windows (hyper-parameter, default 1)
- **strided convolutions:** stride > 1 (stride 2 = feature map are **downsampled** by a factor of 2 (in addition to any changes induced by border effects).

Figure 5.7. 3×3 convolution patches with 2×2 strides (without padding).

5.1.2. The max-pooling operation

- **Pooling:** aggressively **downsample** feature maps (much like strided convolutions).
- MNIST: input feature maps: 26x26, output: 13x13
- **Max pooling:** extract windows from the input feature maps and output the max value of each channel
 - convolution op.: transform local patches via a learned linear convolution kernel
 - usually done with 3×3 windows and no stride (i.e. stride 1)
 - max-pooling op.: transform via a hardcoded max tensor operation.
 - usually done with 2×2 windows and stride 2 (to downsample the feature maps by a factor of 2)

5.1.2. The max-pooling operation

- Why downsample feature maps?

- **reduce the number of feature-map coefficients** to process
 - 30,976 coefficients per sample, dense layer of size 512 on top, that layer would have 15.8 million parameters, small model, overfitting.

- **induce spatial-filter hierarchies** by making successive convolution layers look at increasingly large windows

- the 3×3 windows in the third layer will only contain information coming from 7×7 windows in the initial input, we need the features from the last convolution layer to contain information about the entire image

```
1 model_no_max_pool = models.Sequential()  
2 model_no_max_pool.add(layers.Conv2D(32, (3, 3), activation='relu',  
3                                     input_shape=(28, 28, 1)))  
4 model_no_max_pool.add(layers.Conv2D(64, (3, 3), activation='relu'))  
5 model_no_max_pool.add(layers.Conv2D(64, (3, 3), activation='relu'))
```

```
1 >>> model_no_max_pool.summary()  
2  
3 Layer (type)                      Output Shape       Param #

12 Trainable params: 55,744  
13 Non-trainable params: 0
```

$$22 \times 22 \times 64 = 30976$$

Summary

- Basics of convnets: feature maps, convolution, and max pooling
- Why not strides instead of max pooling & average pooling instead of max pooling
 - features tend to encode the spatial **presence** of some **pattern** or concept over the different tiles of the feature map (hence, the term feature map)
 - it's more informative to look at the **maximal presence** of different features than at their average presence
 - the most reasonable subsampling strategy is to first produce **dense maps** of features (via unstrided convolutions) and then look at the **maximal activation** of the features over small patches, rather than looking at **sparser windows** of the inputs (via strided convolutions) or averaging input patches, which could cause you to miss or dilute feature-presence information.

5.2. Training a convnet from scratch on a small dataset

- cats or dogs (4000, 2000 each, 2000 for training, 1000 for validation and 1000 for testing)
- Strategies (small datasets):
 - training a new model from **scratch** (71%, no regularization, overfitting)
 - data augmentation (82%)
 - **feature extraction** using a pretrained model (90% to 96%)
 - **fine-tuning** a pretrained model (97%)

5.2.1. The relevance of deep learning for small-data problems

- DL Needs lots of data?
 - Partly valid: can find **interesting features** in the training data **on its own**, without any need for **manual feature engineering**, and this can only be achieved when lots of training examples are available (high-dimensional input, e.g. images)
 - Relative: e.g. to the size and depth of the network.
 - not possible to train a convnet to solve a complex problem with just a few tens of samples.
 - a few hundred can potentially suffice if the model is small and well regularized and the task is simple
 - convnets are highly data efficient (learn local, translation-invariant features)
 - Training a convnet from scratch on a very small image dataset will still yield reasonable results without the need for feature engineering
 - DL models are highly repurposable: take a image class model trained on a large-scale dataset and reuse it on a significantly different problem with only minor changes.
 - many **pretrained** models (usually trained on the Image-Net dataset) are now publicly **available**, can be **reused** and work pretty well on **limited data**.

5.2.2. Downloading the data

- Cats vs. Dogs dataset:
 - Kaggle competition, late 2013, won by a convnet, 95% accuracy
 - Here: use less than 10% of the data from the competition.
 - Kaggle dataset: 25 000 images, 12 500 from each class, 543 MB (compressed).
 - Our dataset: training: **2000**, 1000 cats & 1000 dogs, validation (**1000**, 500 each) and test (**1000**, 500 each)

Figure 5.8. Samples from the Dogs vs. Cats dataset. Sizes weren't modified: the samples are heterogeneous in size, appearance, and so on.

Listing 5.4. Copying images to training, validation, and test directories

```

60     dst = os.path.join(validation_dogs_dir, fname)
61     shutil.copyfile(src, dst)
62
63 fnames = ['dog.{}.jpg'.format(i) for i in range(1500, 2000)]
64 for fname in fnames:
65     src = os.path.join(original_dataset_dir, fname)
66     dst = os.path.join(test_dogs_dir, fname)
67     shutil.copyfile(src, dst)
```

5.2.2 (2)

```
1 >>> print('total training cat images:', len(os.listdir(train_cats_dir)))
2 total training cat images: 1000
3
4 >>> print('total training dog images:', len(os.listdir(train_dogs_dir)))
5 total training dog images: 1000
6
7 >>> print('total validation cat images:', len(os.listdir(validation_cats_dir)))
8 total validation cat images: 500
9
10 >>> print('total validation dog images:', len(os.listdir(validation_dogs_dir)))
11 total validation dog images: 500
12
13 >>> print('total test cat images:', len(os.listdir(test_cats_dir)))
14 total test cat images: 500
15
16 >>> print('total test dog images:', len(os.listdir(test_dogs_dir)))
17 total test dog images: 500
```

Balanced binary-classification problem!

5.2.3. Building your network

- convnet: stack of alternated Conv2D (w/ relu activation) and MaxPooling2D layers (4 of each)
- bigger images (150x150) and a more complex problem: larger model (one more Conv2D / MaxPooling2D): increase capacity & reduce last feature map
- Binary-classification problem: single unit with a sigmoid activation (probability for one class or the other)

Listing 5.5. Instantiating a small convnet for dogs vs. cats classification

```
1 from keras import layers
2 from keras import models
3
4 model = models.Sequential()
5 model.add(layers.Conv2D(32, (3, 3), activation='relu',
6                         input_shape=(150, 150, 3)))
7 model.add(layers.MaxPooling2D((2, 2)))
8 model.add(layers.Conv2D(64, (3, 3), activation='relu'))
9 model.add(layers.MaxPooling2D((2, 2)))
10 model.add(layers.Conv2D(128, (3, 3), activation='relu'))
11 model.add(layers.MaxPooling2D((2, 2)))
12 model.add(layers.Conv2D(128, (3, 3), activation='relu'))
13 model.add(layers.MaxPooling2D((2, 2)))
14 model.add(layers.Flatten())
15 model.add(layers.Dense(512, activation='relu'))
16 model.add(layers.Dense(1, activation='sigmoid'))
```

5.2.3. Building your network (2)

- The depth of the feature maps progressively increases in the network (from 32 to 128), whereas the size of the feature maps decreases (from 148×148 to 7×7). This is a pattern you'll see in almost all convnets.

```
1 >>> model.summary()

5.2.3. Building your network (3)

- sigmoid unit and binary cross-entropy as the loss
- RMSprop optimizer

Listing 5.6. Configuring the model for training

```
1 from keras import optimizers  
2  
3 model.compile(loss='binary_crossentropy',  
4                 optimizer=optimizers.RMSprop(lr=1e-4),  
5                 metrics=['acc'])
```

Table 4.1. Choosing the right last-layer activation and loss function for your model

Problem type	Last-layer activation	Loss function
Binary classification	sigmoid	binary_crossentropy
Multiclass, single-label classification	softmax	categorical_crossentropy
Multiclass, multilabel classification	sigmoid	binary_crossentropy
Regression to arbitrary values	None	mse
Regression to values between 0 and 1	sigmoid	mse or binary_crossentropy

5.2.4. Data preprocessing

- **Steps** for getting the data into the network:

- Read the picture files.
- Decode the JPEG content to RGB grids of pixels.
- Convert these into floating-point tensors.
- Rescale the pixel values (between 0 and 255) to the [0, 1] interval (as you know, neural networks prefer to deal with small input values).
- Keras utilities:
 - `from keras.preprocessing.image import ImageDataGenerator`

Listing 5.7. Using `ImageDataGenerator` to read images from directories

```
1 from keras.preprocessing.image import ImageDataGenerator
2
3 train_datagen = ImageDataGenerator(rescale=1./255)
4 test_datagen = ImageDataGenerator(rescale=1./255)
5
6 train_generator = train_datagen.flow_from_directory(
7     train_dir,
8     target_size=(150, 150),
9     batch_size=20,
10    class_mode='binary')
11
12 validation_generator = test_datagen.flow_from_directory(
13     validation_dir,
14     target_size=(150, 150),
15     batch_size=20,
16     class_mode='binary')
```

5.2.4. Data preprocessing (2)

- generator similar to iterator
 - for ... in, built using the **yield** operator
- train_generator yields **batches** of 150×150 RGB images (shape (20, 150, 150, 3)) and binary labels (shape (20,))

UNDERSTANDING PYTHON GENERATORS

A *Python generator* is an object that acts as an iterator: it's an object you can use with the `for ... in` operator. Generators are built using the `yield` operator.

Here is an example of a generator that yields integers:

```
1 def generator():
2     i = 0
3     while True:
4         i += 1
5         yield i
6
7 for item in generator():
8     print(item)
9     if item > 4:
10        break
```

copy

It prints this:

```
1 >>> for data_batch, labels_batch in train_generator:
2
3 >>>     print('data batch shape:', data_batch.shape)
4
5 >>>     print('labels batch shape:', labels_batch.shape)
6
>>>     break
data batch shape: (20, 150, 150, 3)
labels batch shape: (20,)
```

5.2.4. Data preprocessing (3)

- Fit the model to the data using the generator
- **fit_generator** method equivalent to **fit**
 - 1st argument is a **generator** that will yield **batches** of inputs and targets indefinitely
 - 2nd argument: how many samples (i.e. gradient descent steps, 20 images each) to draw from the generator before declaring an epoch over
 - Save your models after training

Listing 5.8. Fitting the model using a batch generator

```
1 history = model.fit_generator(  
2     train_generator,  
3     steps_per_epoch=100,      100 x 20 = 2000  
4     epochs=30,  
5     validation_data=validation_generator,  
6     validation_steps=50)      50 x 20 = 1000
```

Listing 5.9. Saving the model

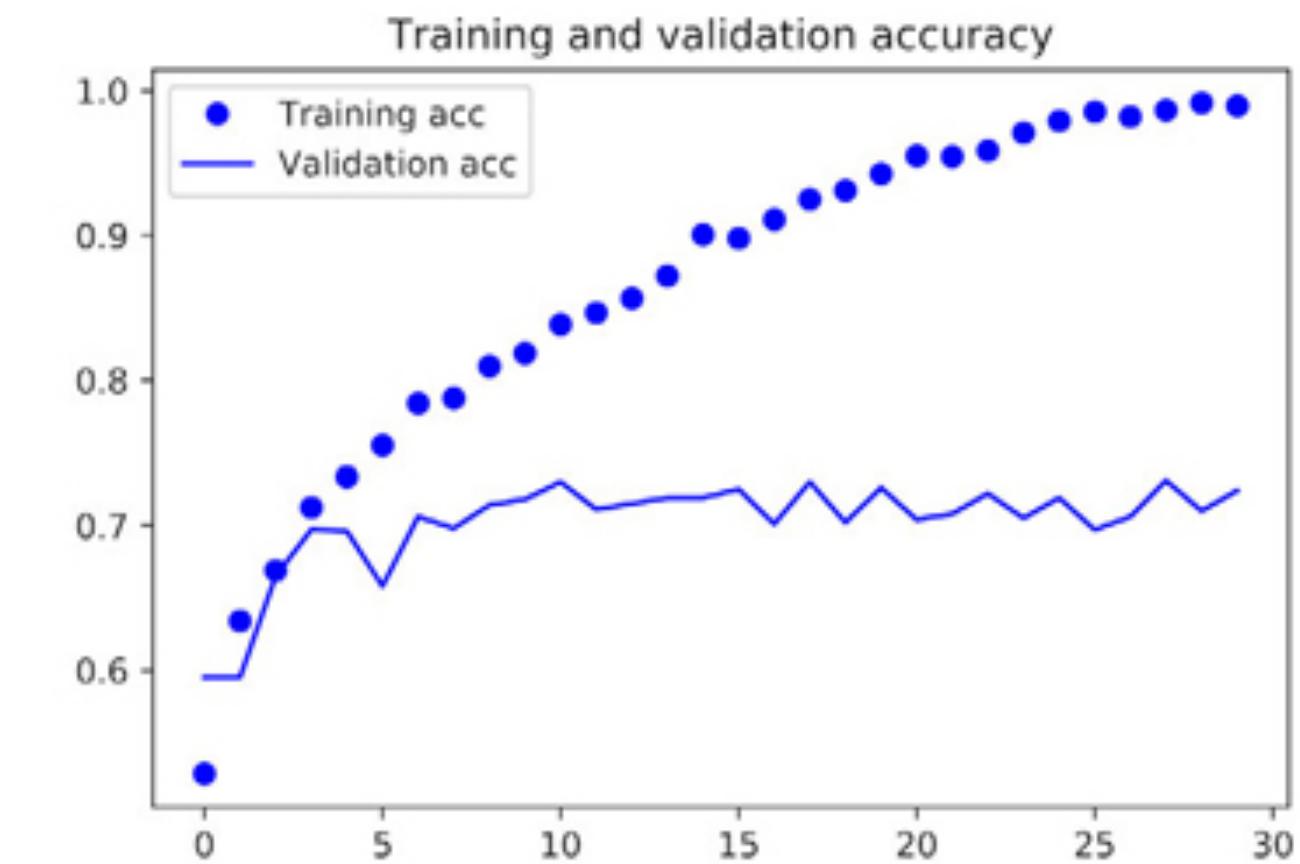

```
1 model.save('cats_and_dogs_small_1.h5')
```

5.2.4. Data preprocessing (4)

- Plots are characteristic of **overfitting**: training accuracy increases to nearly 100%, validation accuracy stalls at 70–72%, the validation loss reaches its minimum after only five epochs and then stalls
- **Mitigate** overfitting: dropout, weight decay (L2 regularization) and **data augmentation**

Listing 5.10. Displaying curves of loss and accuracy during training

```
1 import matplotlib.pyplot as plt
2
3 acc = history.history['acc']
4 val_acc = history.history['val_acc']
5 loss = history.history['loss']
6 val_loss = history.history['val_loss']
7
8 epochs = range(1, len(acc) + 1)
9
10 plt.plot(epochs, acc, 'bo', label='Training acc')
11 plt.plot(epochs, val_acc, 'b', label='Validation acc')
12 plt.title('Training and validation accuracy')
13 plt.legend()
14
15 plt.figure()
16
17 plt.plot(epochs, loss, 'bo', label='Training loss')
18 plt.plot(epochs, val_loss, 'b', label='Validation loss')
19 plt.title('Training and validation loss')
20 plt.legend()
21
22 plt.show()
```

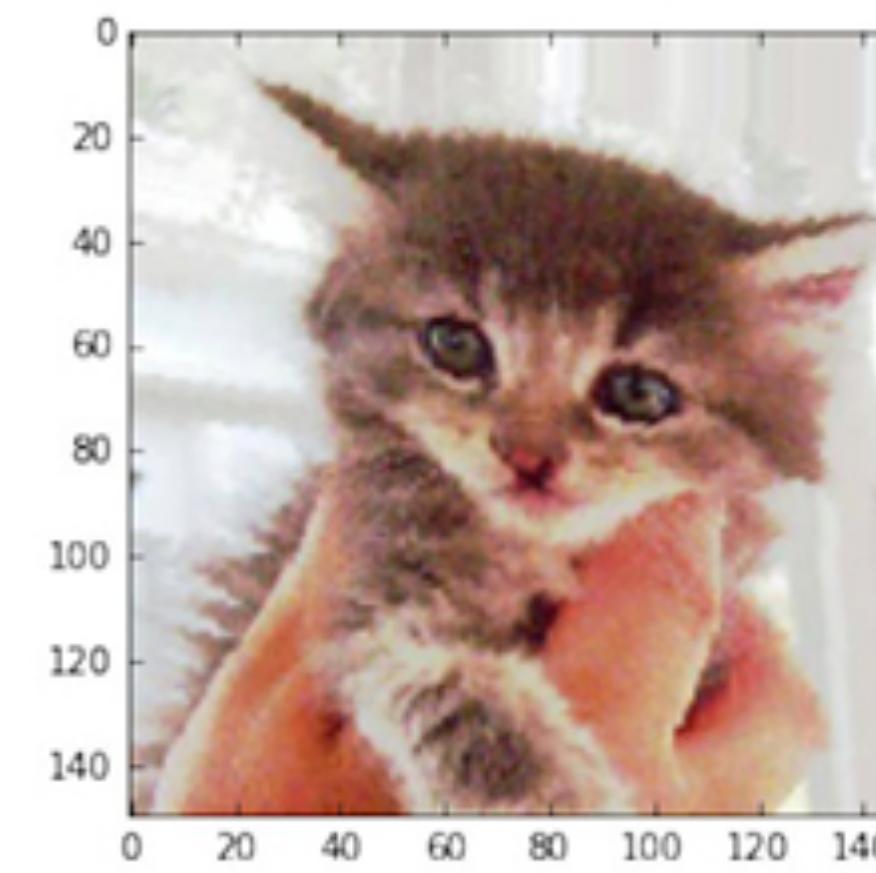

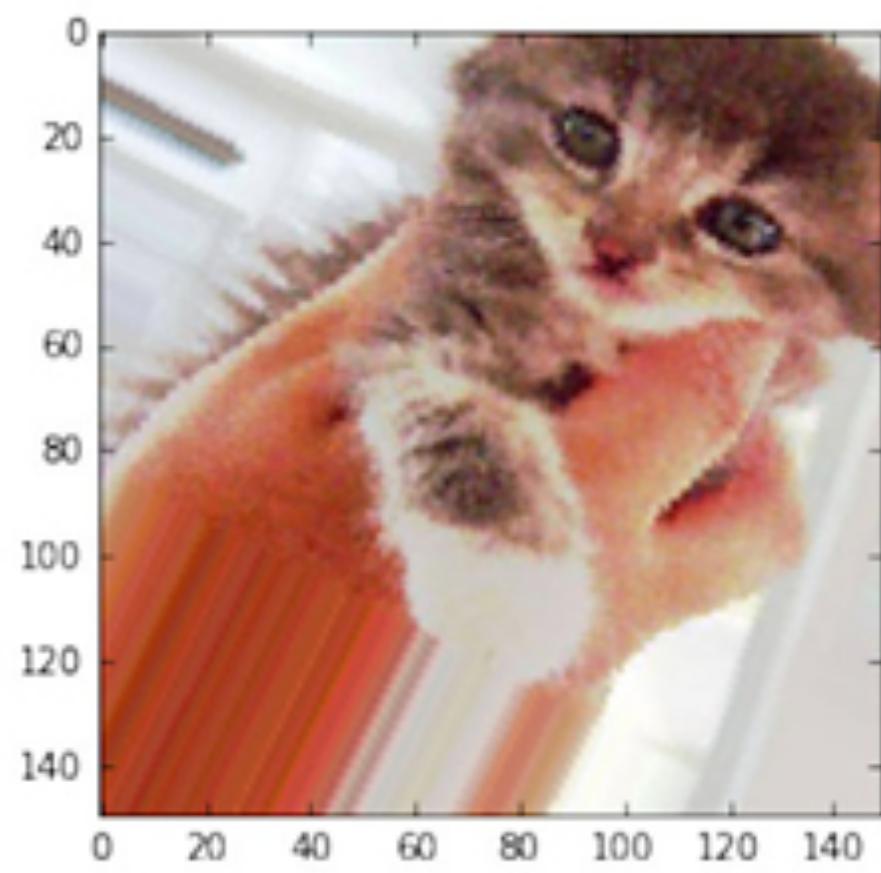

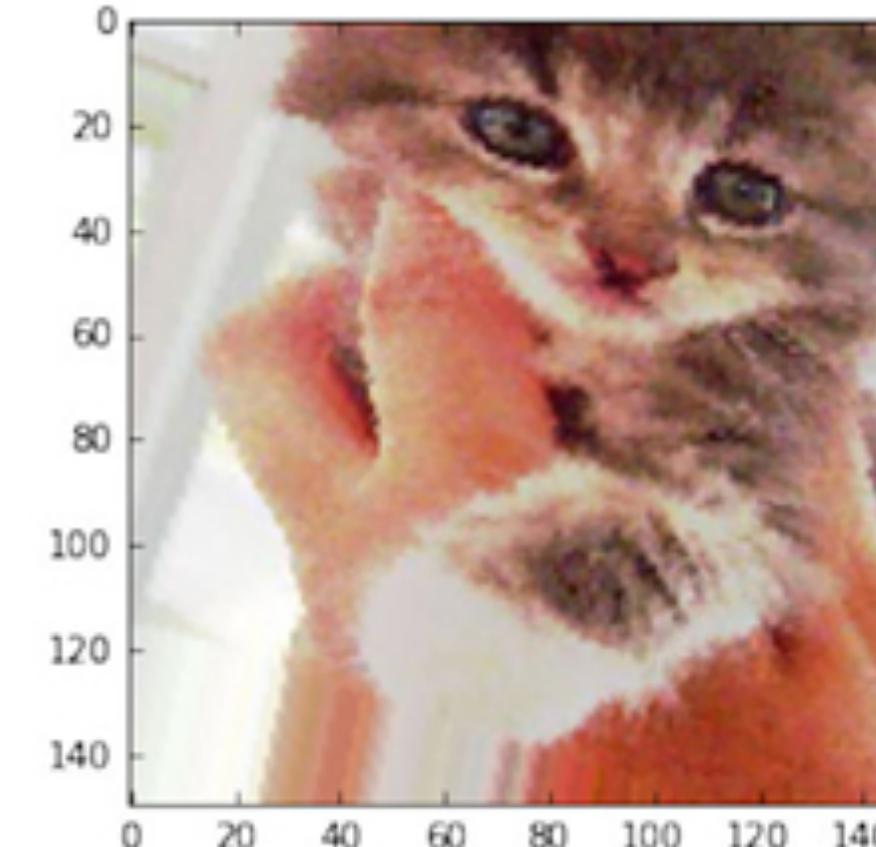

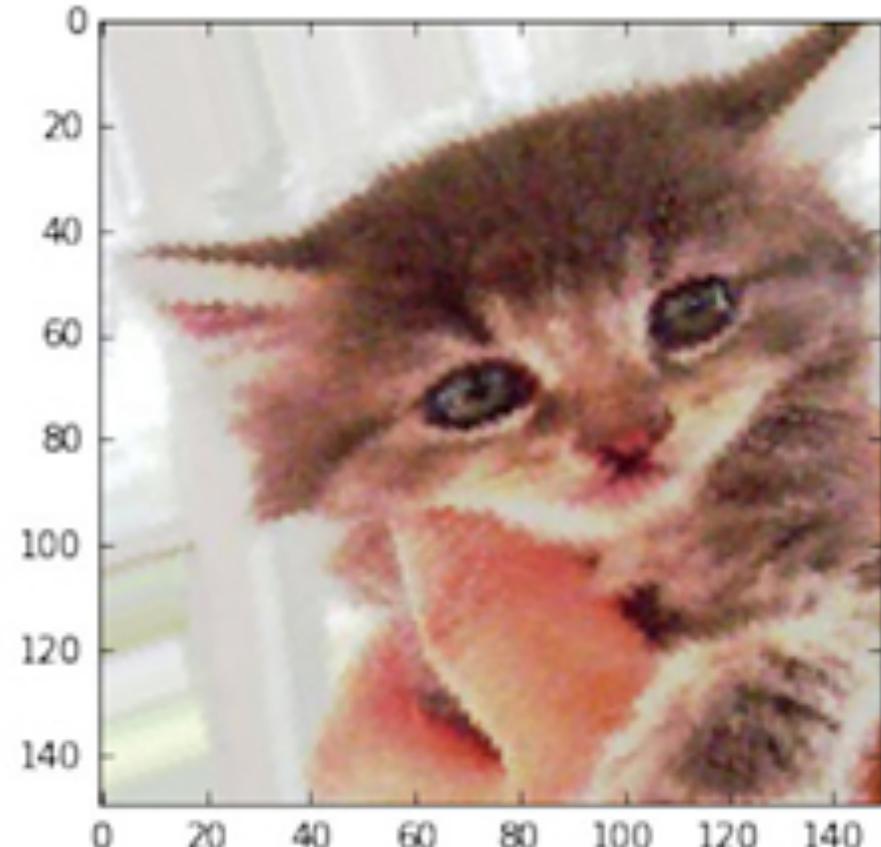

5.2.5. Using data augmentation

- **Overfitting:** too few samples, unable to generalize to new data
- Given **infinite** data, your model would be **exposed** to every possible **aspect** of the data distribution at hand: you would never overfit.
- Data **augmentation**: generating more (believable-looking) training data from existing training samples via transformations without changing the label. Goal is to never see the exact same picture twice during training exposing the model to more aspects of the data and generalize better.
- Keras: use an **ImageDataGenerator** yielding a number of random transformations.

Listing 5.11. Setting up a data augmentation configuration via

```
1 datagen = ImageDataGenerator(  
2     rotation_range=40,  
3     width_shift_range=0.2,  
4     height_shift_range=0.2,  
5     shear_range=0.2,  
6     zoom_range=0.2,  
7     horizontal_flip=True,  
8     fill_mode='nearest')
```

5.2.5. Using data augmentation (2)

Listing 5.12. Displaying some randomly augmented training images

```
1 from keras.preprocessing import image
2
3 fnames = [os.path.join(train_cats_dir, fname) for
4     fname in os.listdir(train_cats_dir)]
5
6 img_path = fnames[3]
7
8 img = image.load_img(img_path, target_size=(150, 150))
9
10 x = image.img_to_array(img)
11 x = x.reshape((1,) + x.shape)
12
13 i = 0
14 for batch in datagen.flow(x, batch_size=1):
15     plt.figure(i)
16     imgplot = plt.imshow(image.array_to_img(batch[0]))
17     i += 1
18     if i % 4 == 0:
19         break
20
21 plt.show()
```

5.2.5. Using data augmentation (3)

Listing 5.13. Defining a new convnet that includes dropout

```
1 model = models.Sequential()
2 model.add(layers.Conv2D(32, (3, 3), activation='relu',
3                         input_shape=(150, 150, 3)))
4 model.add(layers.MaxPooling2D((2, 2)))
5 model.add(layers.Conv2D(64, (3, 3), activation='relu'))
6 model.add(layers.MaxPooling2D((2, 2)))
7 model.add(layers.Conv2D(128, (3, 3), activation='relu'))
8 model.add(layers.MaxPooling2D((2, 2)))
9 model.add(layers.Conv2D(128, (3, 3), activation='relu'))
10 model.add(layers.MaxPooling2D((2, 2)))
11 model.add(layers.Flatten())
12 model.add(layers.Dropout(0.5))
13 model.add(layers.Dense(512, activation='relu'))
14 model.add(layers.Dense(1, activation='sigmoid'))
15
16 model.compile(loss='binary_crossentropy',
17                 optimizer=optimizers.RMSprop(lr=1e-4),
18                 metrics=['acc'])
```

Listing 5.15. Saving the model

```
1 model.save('cats_and_dogs_small_2.h5')
```

Listing 5.14. Training the convnet using data-augmentation generators

```
1 train_datagen = ImageDataGenerator(
2     rescale=1./255,
3     rotation_range=40,
4     width_shift_range=0.2,
5     height_shift_range=0.2,
6     shear_range=0.2,
7     zoom_range=0.2,
8     horizontal_flip=True,)

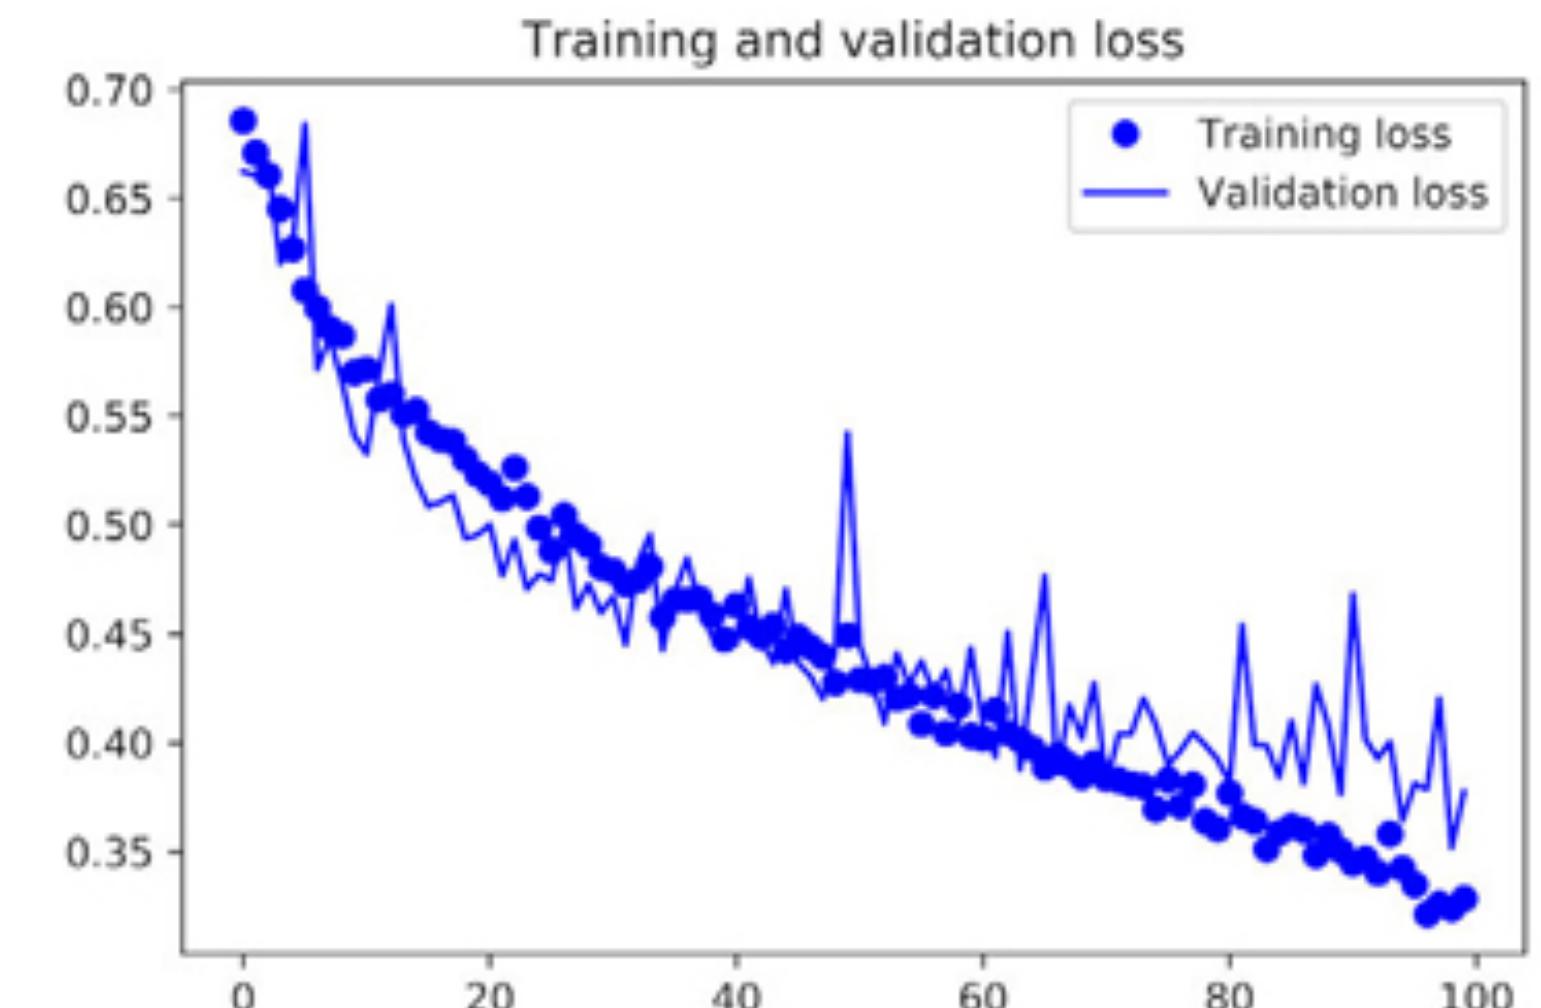

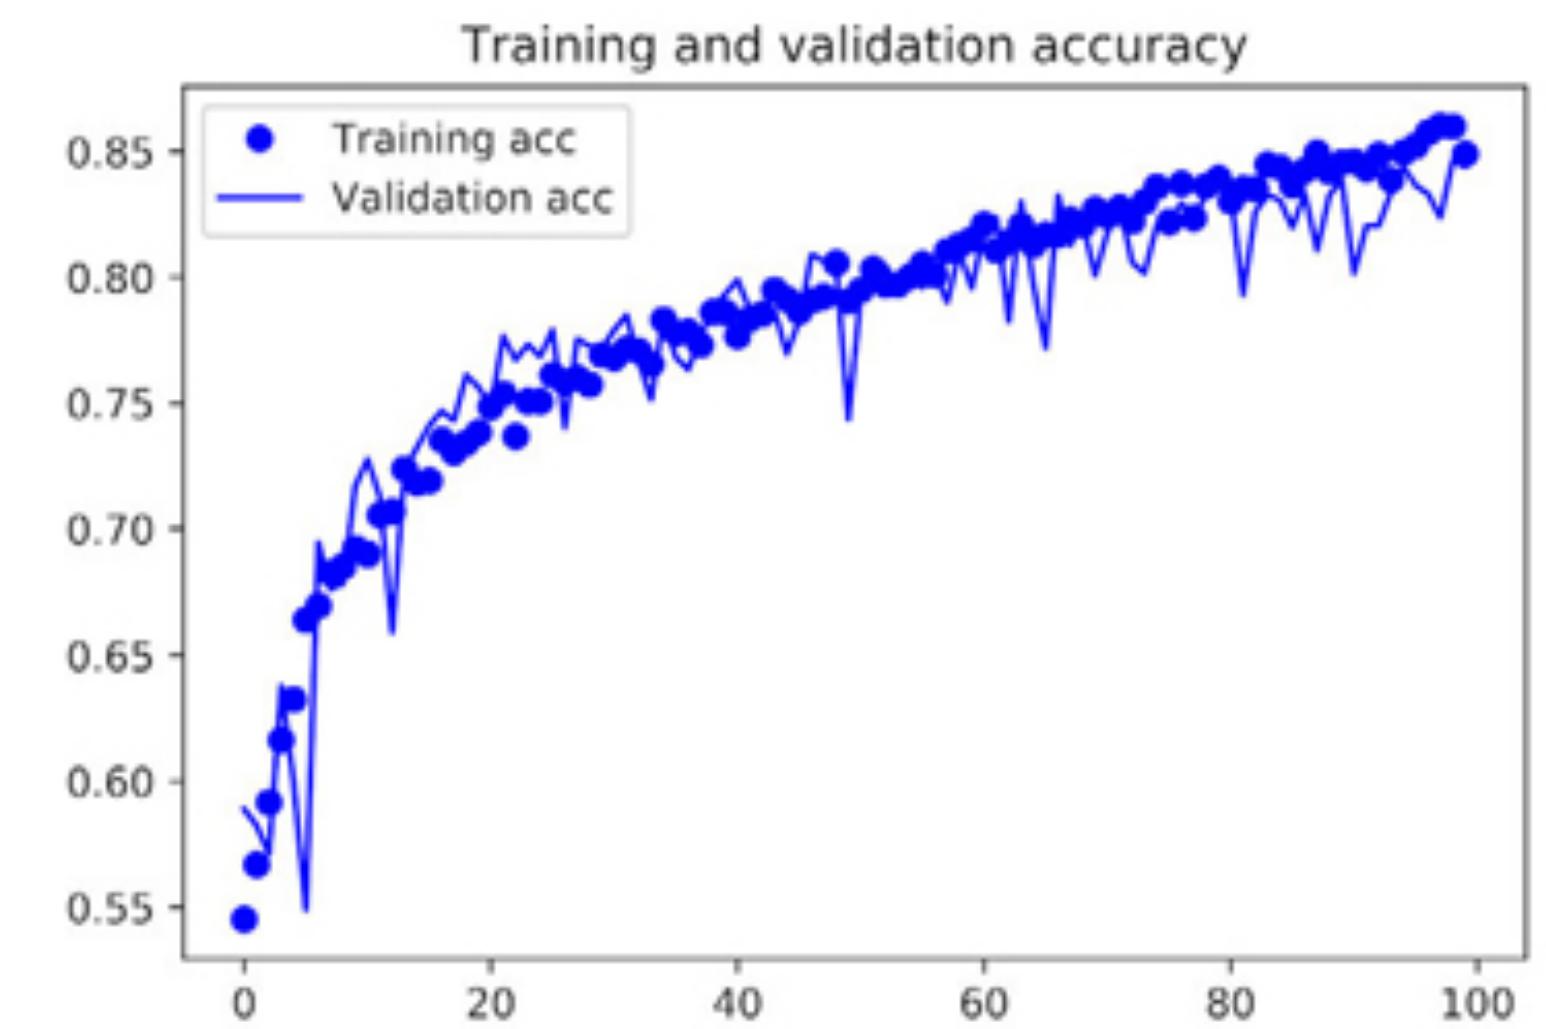

9
10 test_datagen = ImageDataGenerator(rescale=1./255)
11
12 train_generator = train_datagen.flow_from_directory(
13     train_dir,
14     target_size=(150, 150),
15     batch_size=32,
16     class_mode='binary')

17
18 validation_generator = test_datagen.flow_from_directory(
19     validation_dir,
20     target_size=(150, 150),
21     batch_size=32,
22     class_mode='binary')

23
24 history = model.fit_generator(
25     train_generator,
26     steps_per_epoch=100,
27     epochs=100,
28     validation_data=validation_generator,
29     validation_steps=50)
```

5.2.5. Using data augmentation (4)

- Results with data augmentation and dropout:
 - No evidence of overfitting: training curves are closely tracking the validation curves, accuracy of 82%
 - By exploring further regularization techniques and tuning the network's parameters (e.g. number of filters per convolution layer, number of layers in the network etc.): up to 86% or 87% accuracy.
 - Difficult to go any higher just by training your own convnet from **scratch** (too little data), to improve your accuracy you'll have to use a **pretrained model**

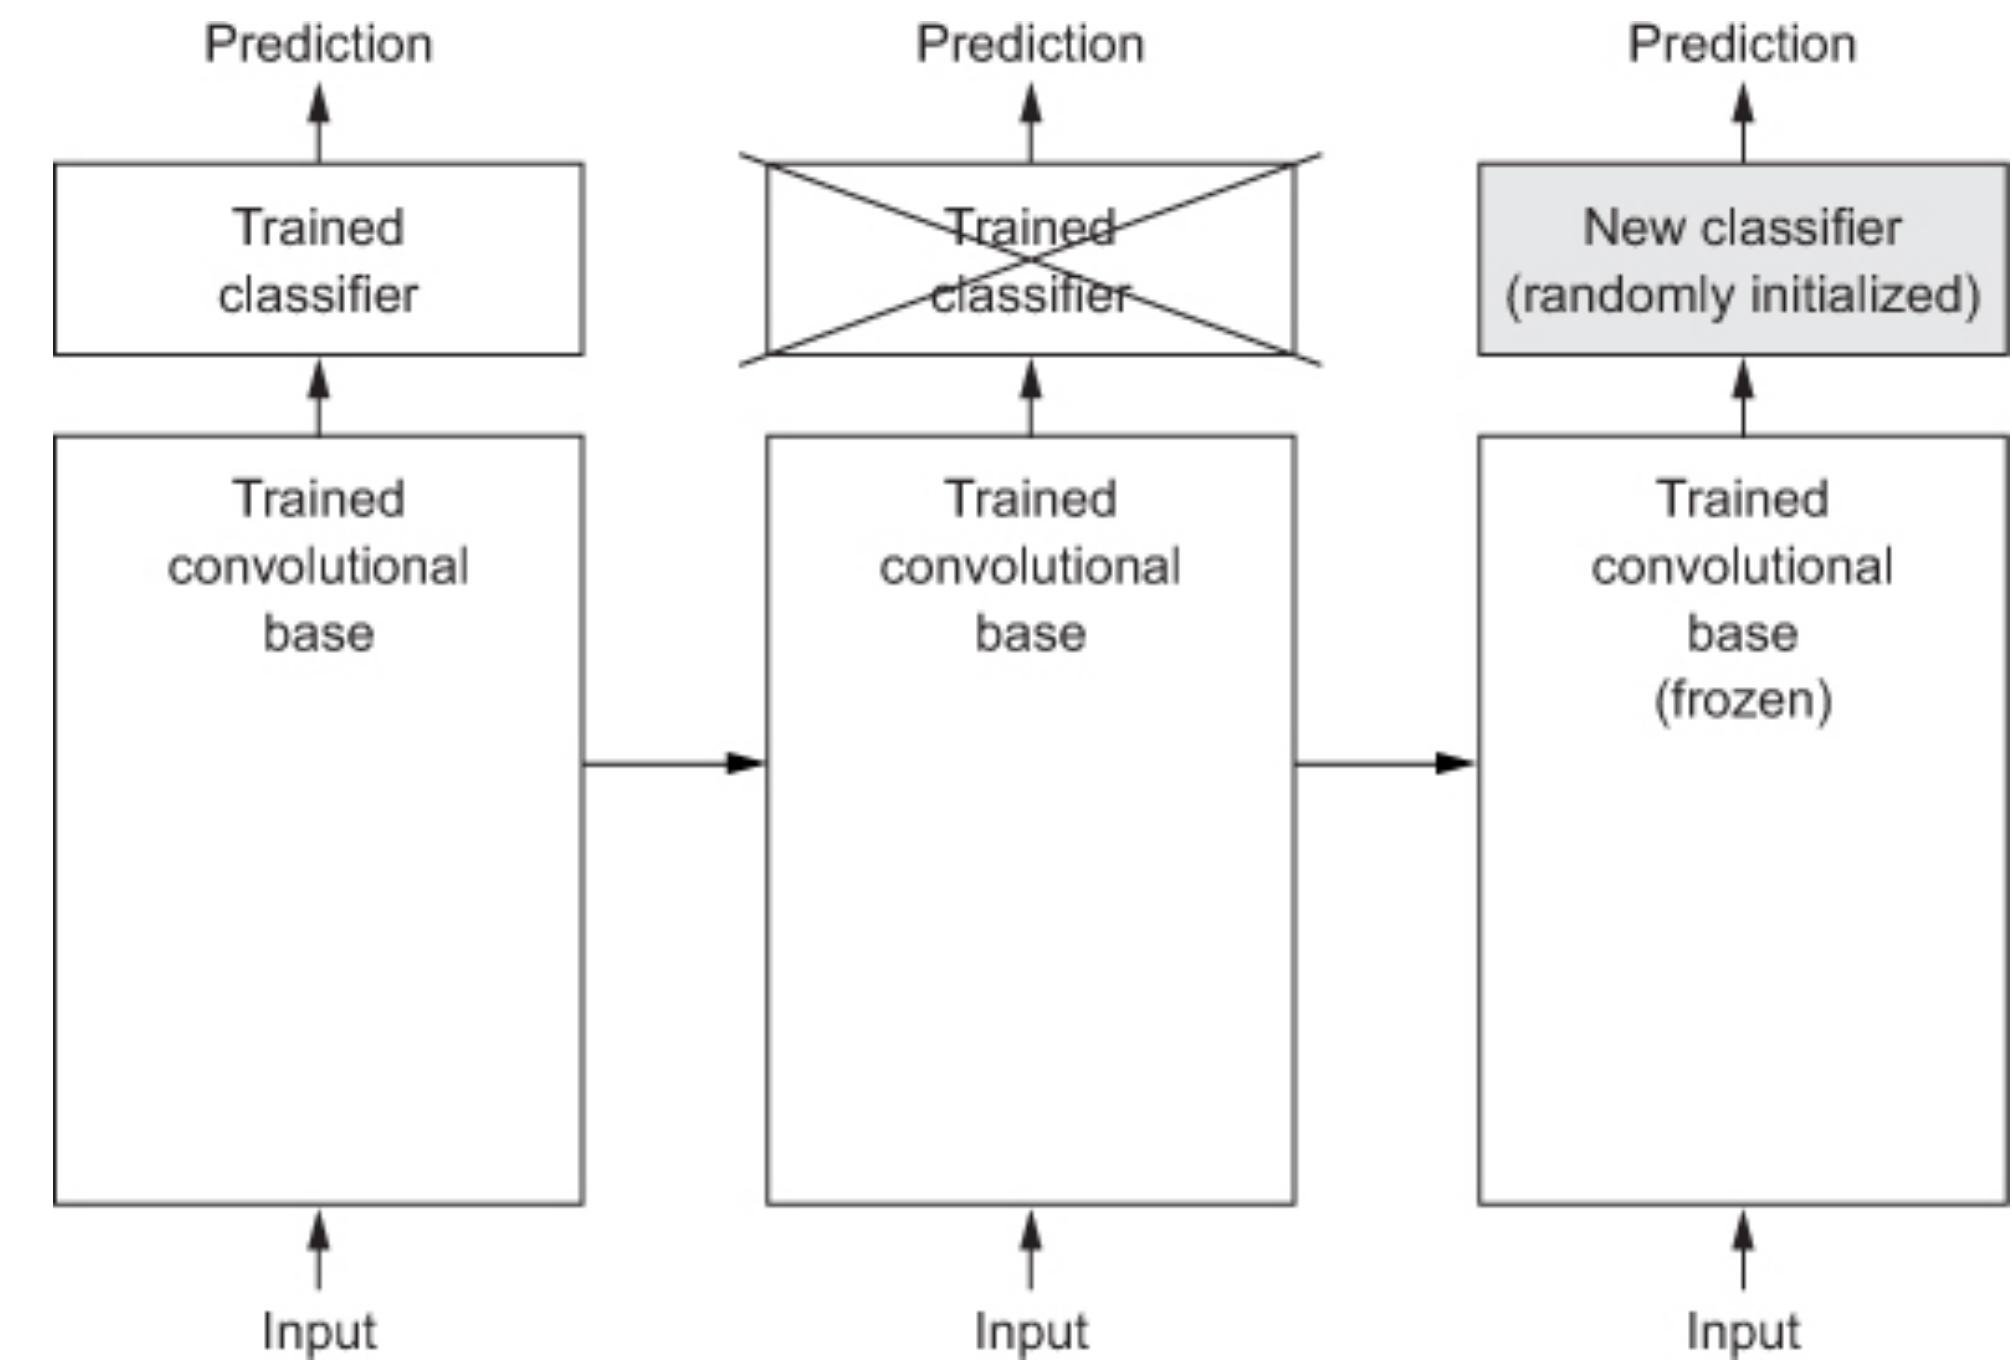

5.3. Using a pretrained convnet

- Pretrained network: **saved** network that was previously trained on a **large** dataset
- If dataset is **large** enough and **general** enough, then the **spatial hierarchy of features learned** by the pretrained network can effectively act as a **generic model** of the **visual world**.
- Train a network on Image-Net (mostly animals and everyday objects) and then **repurpose** this trained network for something completely different, e.g. identifying furniture items in pictures or finding structures in ultrasound images.
- This **portability of learned features** across different problems is a key advantage of deep learning compared to many older, shallow-learning approaches, and it makes deep learning very **effective** also for small-data problems.
- ImageNet: 1.4 million labeled images and 1,000 different classes (contains many animal classes, including different species of cats and dogs)
- Will use VGG16 architecture (others: ResNet, Inception, Inception-ResNet, Xception, and so on)
- **Pretrained** networks can be used in two different ways: **feature extraction** and **fine-tuning**

5.3.1. Feature extraction

- Feature extraction: keep the **convolutional base** of a previously trained network (running the new data through it) and train a new **classifier** (on top of the output).
- The representations learned by the convolutional **base**: feature maps or **presence maps** of **generic** concepts over a picture. Representations learned by the **classifier** will necessarily be **specific** to the set of classes on which the model was trained (also, contain no information about **where** objects are located in the input image)
- Level of generality and reusability depends on the depth of the layer: early layer extract local, highly **generic** feature maps (such as visual edges, colors, and textures), higher layers extract more-**abstract** concepts (such as “cat ear” or “dog eye”). Depending on the dataset - not use the entire convolutional base.

Figure 5.14. Swapping classifiers while keeping the same convolutional base

5.3.1. Feature extraction (2)

- Keras: prepackaged image-classification models (**VGG16**, VGG19, ResNet50, Inception V3, Xception, MobileNet)
- The final feature map has shape (4, 4, 512), two alternatives:
 - Running the convolutional base over your dataset, recording its output to a Numpy array on disk, and then using this data as input to a standalone, densely connected classifier (back to start)
 - Extending the model you have (conv_base) by adding Dense layers on top (allows data augmentation).

Listing 5.16. Instantiating the VGG16 convolutional base

```
1 from keras.applications import VGG16
2
3 conv_base = VGG16(weights='imagenet',
4                   include_top=False,
5                   input_shape=(150, 150, 3))
```

```

90% accuracy (better than from scratch approach), plots also indicate overfitting

5.3.1: Feature extraction with data augmentation

- Extending the conv_base model and running it end to end on the inputs.
- Much slower and more expensive (need a GPU)
- Part of a model can be added just like a layer
- The convolutional base of VGG16 has 14,714,688 parameters, the added classifier has 2 mill.

Listing 5.20. Adding a densely connected classifier on top of the convolutional base

```
1 from keras import models
2 from keras import layers
3
4 model = models.Sequential()
5 model.add(conv_base)
6 model.add(layers.Flatten())
7 model.add(layers.Dense(256, activation='relu'))
8 model.add(layers.Dense(1, activation='sigmoid'))
```

```
1 >>> model.summary()
2 Layer (type)                      Output Shape           Param #
3 =====
4 vgg16 (Model)                    (None, 4, 4, 512)    14714688
5
6 flatten_1 (Flatten)               (None, 8192)          0
7
8 dense_1 (Dense)                  (None, 256)           2097408
9
10 dense_2 (Dense)                 (None, 1)            257
11 =====
12 Total params: 16,812,353
13 Trainable params: 16,812,353
14 Non-trainable params: 0
```

5.3.1: Feature extraction with data augmentation (2)

```
1 >>> print('This is the number of trainable weights '
2       'before freezing the conv base:', len(model.trainable_weights))
3 This is the number of trainable weights before freezing the conv base: 30
4 >>> conv_base.trainable = False
5 >>> print('This is the number of trainable weights '
6       'after freezing the conv base:', len(model.trainable_weights))
7 This is the number of trainable weights after freezing the conv base: 4
```

- In Keras, you freeze a model by setting its **trainable** attribute to False
- Only the weights from the two Dense layers will be trained, four weight tensors: two per layer (the main weight matrix and the bias vector).
- Now you can start to train your model (with data-augmentation).

Listing 5.21. Training the model end to end with a frozen convolutional base

```
1  from keras.preprocessing.image import ImageDataGenerator
2  from keras import optimizers
3
4  train_datagen = ImageDataGenerator(
5      rescale=1./255,
6      rotation_range=40,
7      width_shift_range=0.2,
8      height_shift_range=0.2,
9      shear_range=0.2,
10     zoom_range=0.2,
11     horizontal_flip=True,
12     fill_mode='nearest')
13
14 test_datagen = ImageDataGenerator(rescale=1./255)
15
16 train_generator = train_datagen.flow_from_directory(
17     train_dir,
18     target_size=(150, 150),
19     batch_size=20,
20     class_mode='binary')
21
22 validation_generator = test_datagen.flow_from_directory(
23     validation_dir,
24     target_size=(150, 150),
25     batch_size=20,
26     class_mode='binary')
27
28 model.compile(loss='binary_crossentropy',
29                 optimizer=optimizers.RMSprop(lr=2e-5),
30                 metrics=['acc'])
31
32 history = model.fit_generator(
33     train_generator,
34     steps_per_epoch=100,
35     epochs=30,
36     validation_data=validation_generator,
37     validation_steps=50)
```

5.3.1: Feature extraction with data augmentation (3)

- We get an accuracy (validation) of about **96%** (much better than the train from scratch approach).

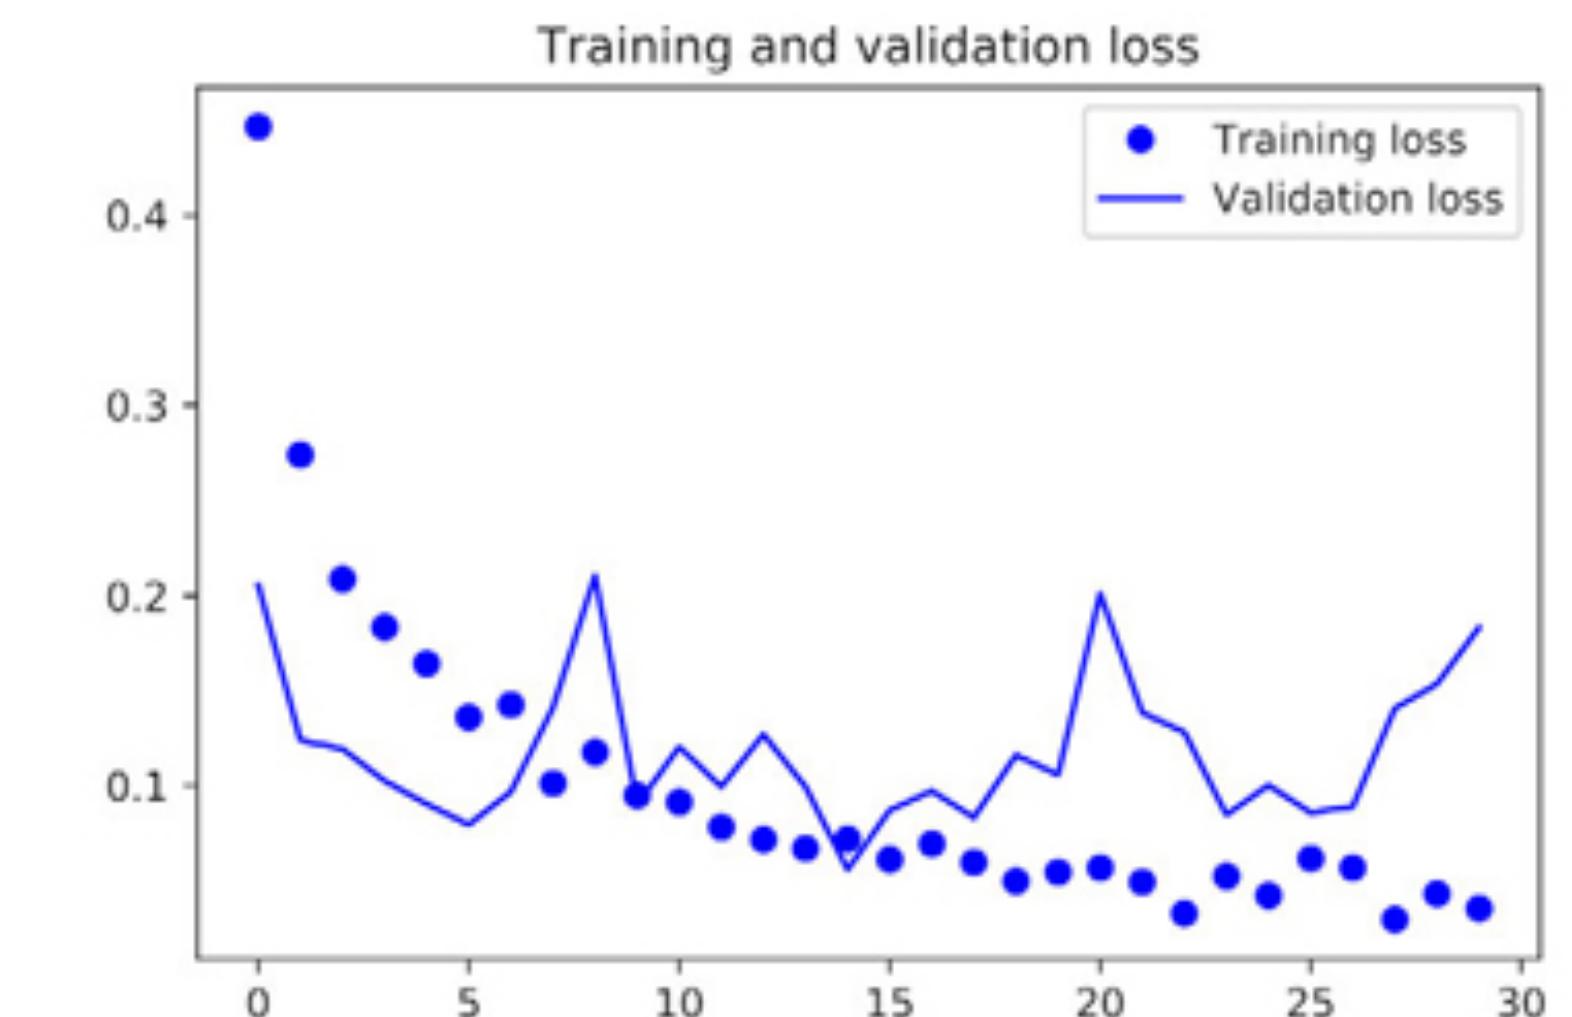

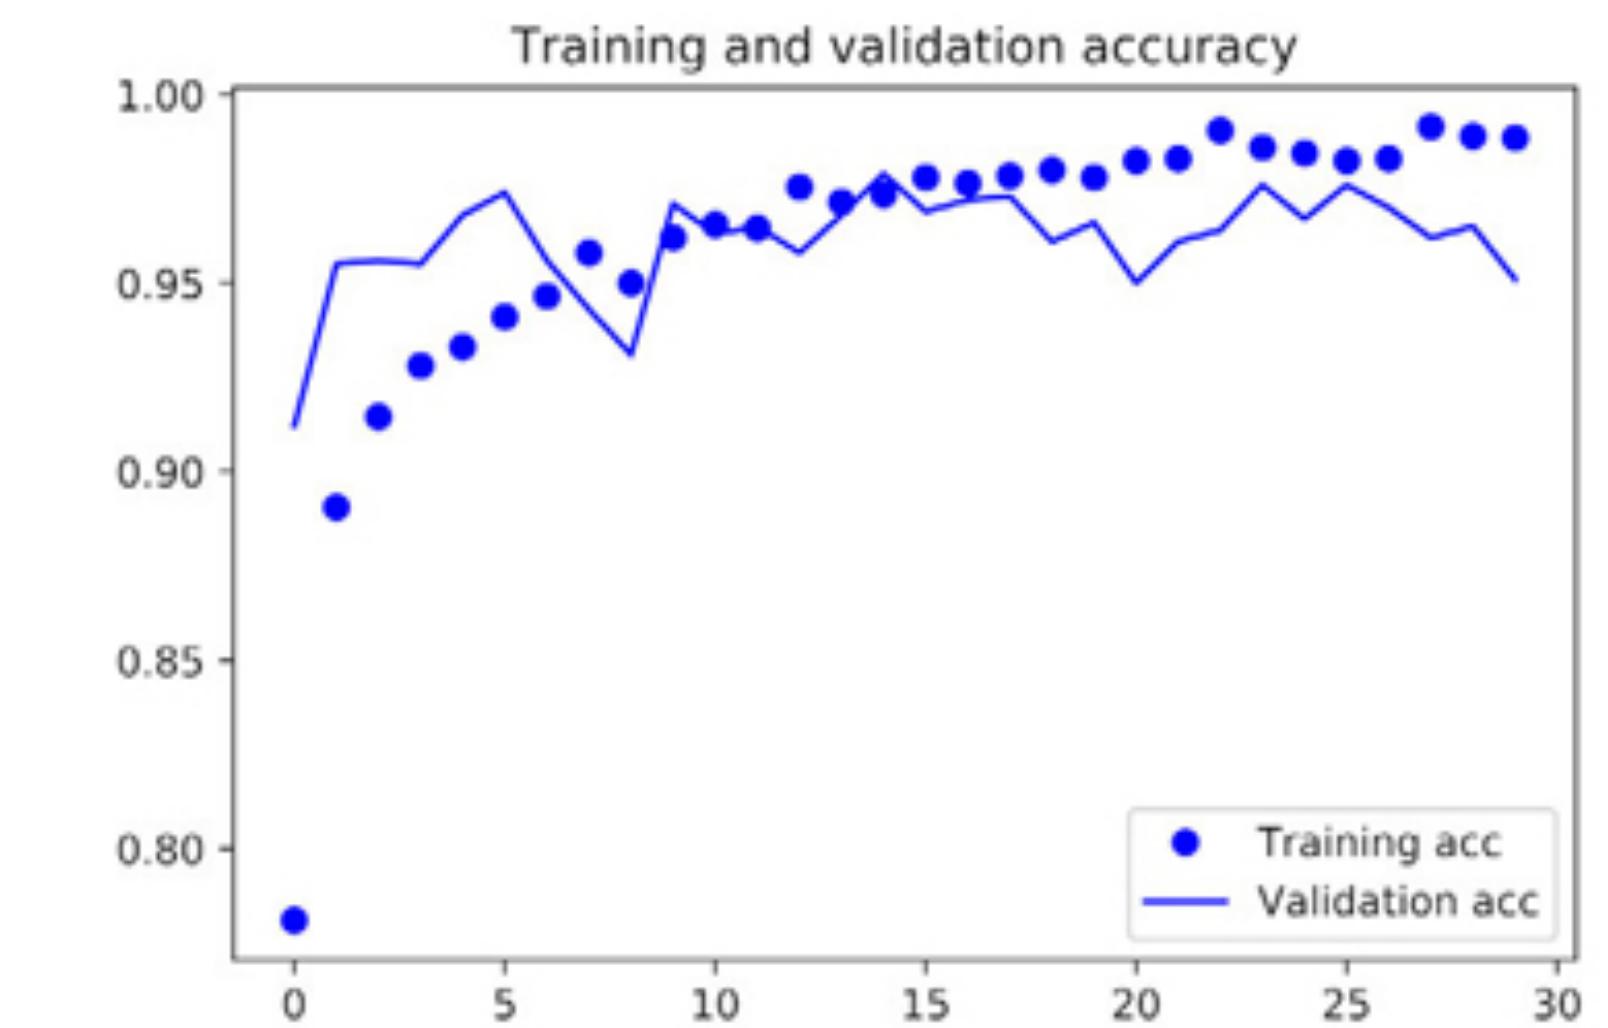

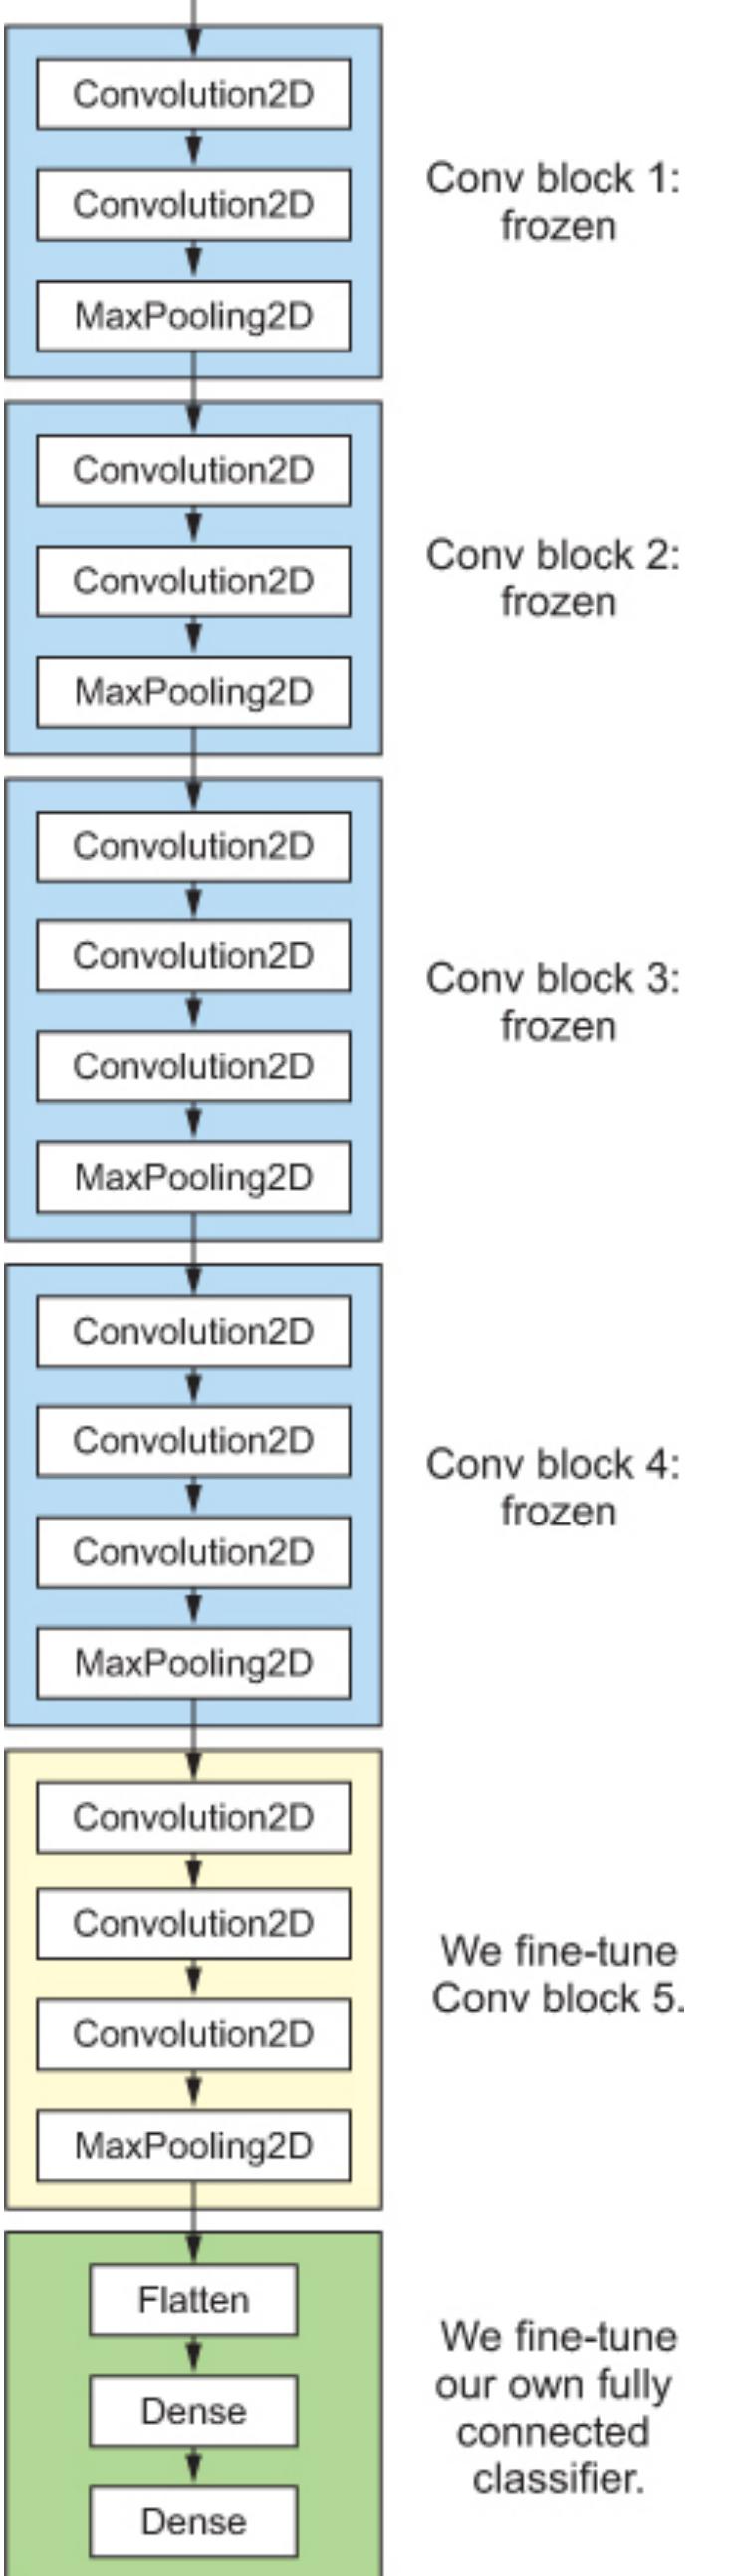

Figure 5.19. Fine-tuning
the last convolutional block
of the VGG16 network

5.3.2. Fine-tuning

- **Fine-tuning** (alt. model reuse method):
 - unfreezing a few of the top layers of a frozen model base
 - jointly training both the newly added part of the model (in this case, the fully connected classifier) and these top layers
 - slightly adjusts the more abstract representations of the model being reused, in order to make them more relevant for the problem at hand

5.3.2. Fine-tuning (2)

- A reminder of the convolutional base
- Steps for fine-tuning a network (NB: it's only possible to fine-tune the top layers of the convolutional base once the classifier on top has already been trained)
 - Add your custom network on top of an already-trained base network.
 - Freeze the base network.
 - Train the part you added.
 - **Unfreeze some layers in the base network.**
 - Jointly train both these layers and the part you added.
- Layers up to block4_pool should be frozen, and the layers block5_conv1, block5_conv2, and block5_conv3 should be trainable.

```
1 >>> conv_base.summary()

40
41 block5_pool (MaxPooling2D) (None, 4, 4, 512)   0
42 =====
43 Total params: 14714688
```

5.3.2. Fine-tuning (3)

- Why not fine-tune more layers? Why not fine-tune the entire convolutional base?
 - Earlier layers encode more-generic, reusable features, whereas layers higher up encode more-specialized features (which needs to be repurposed)
 - The more parameters you're training, the more you're at risk of overfitting, especially when you attempt to train it on a small dataset.
- Good strategy to fine-tune only the top two or three layers
- Starting from where you left off in the previous example:
 - Freeze the last block in the base
 - Fine-tuning the network using a very low learning rate

Listing 5.22. Freezing all layers up to a specific one

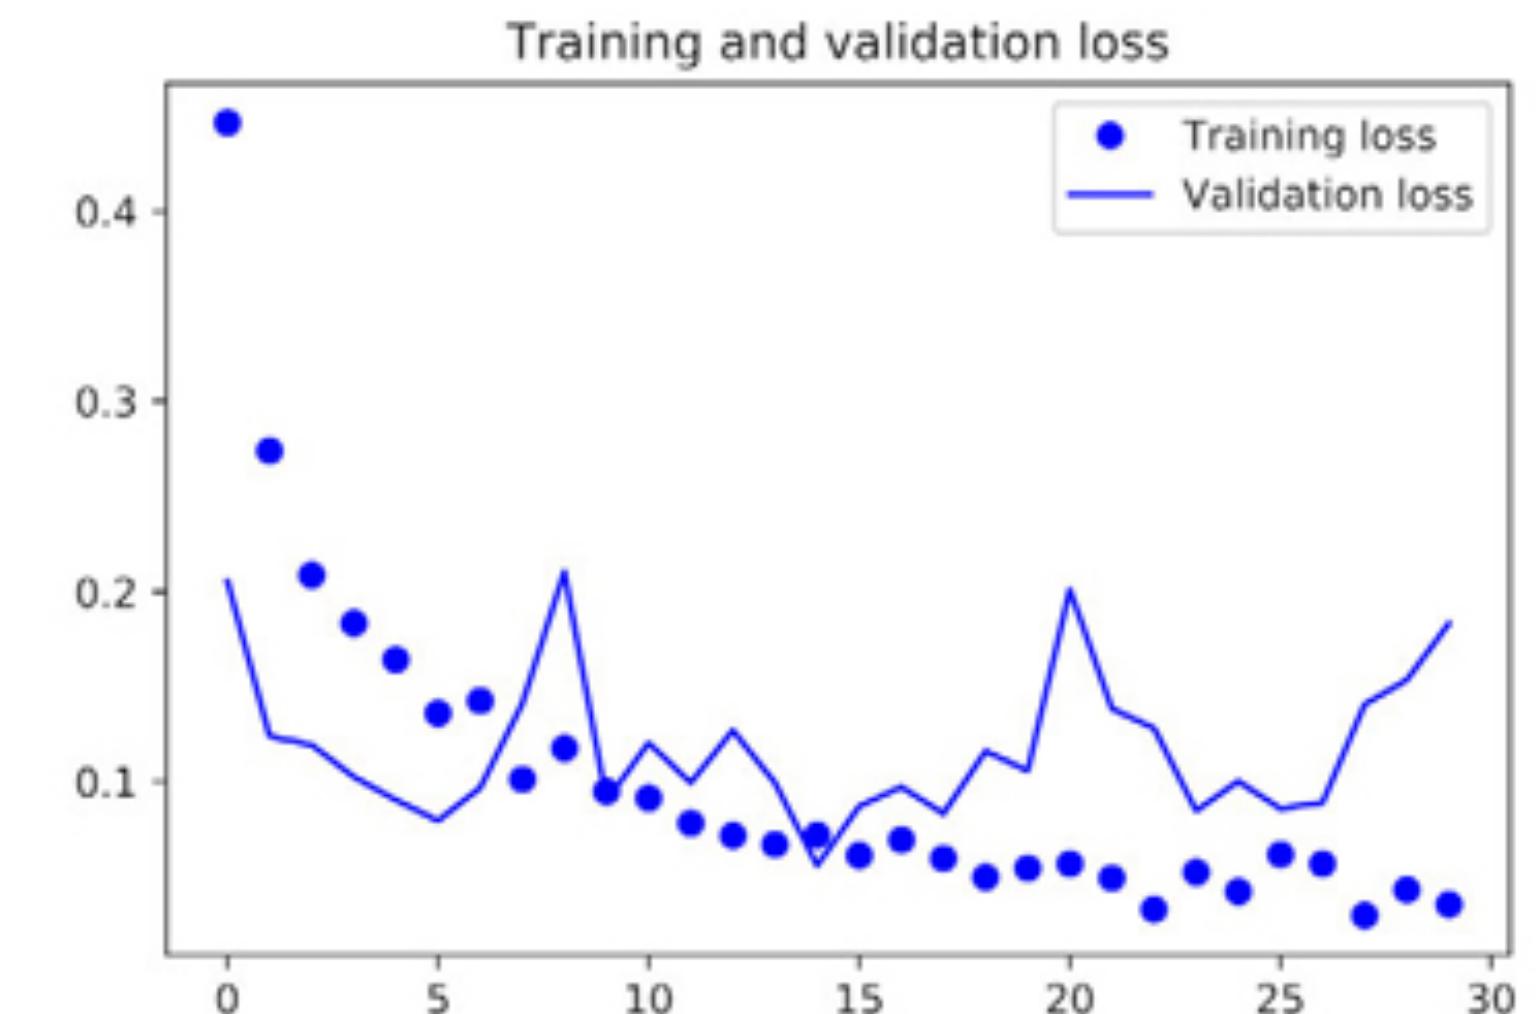

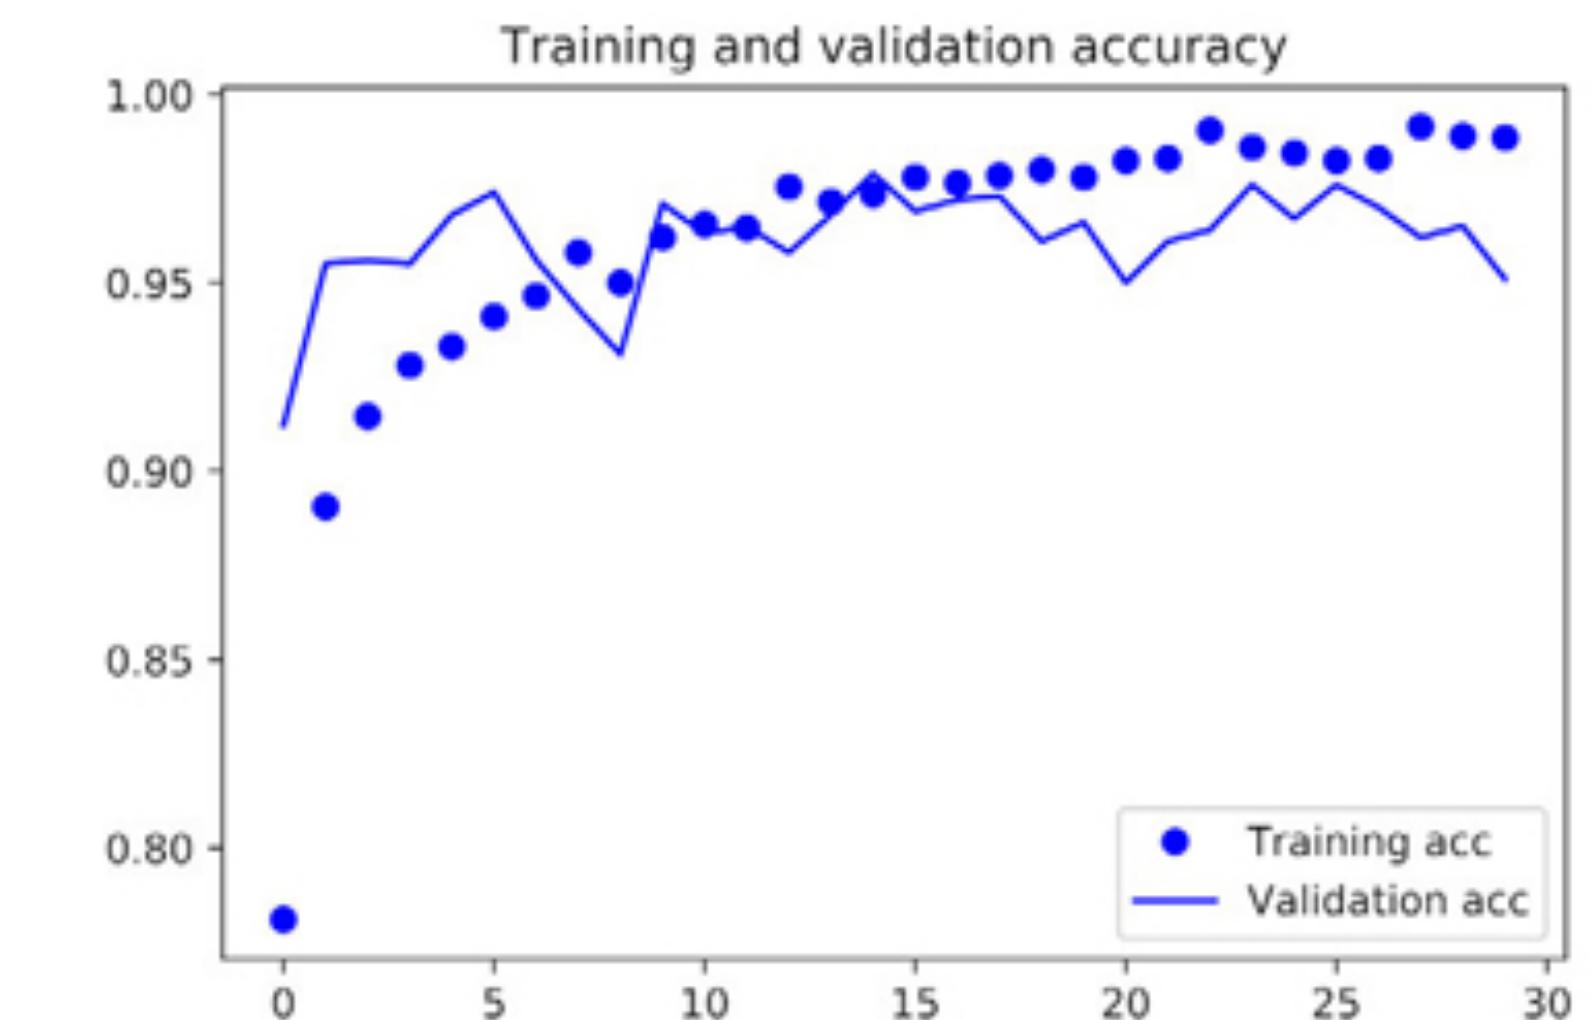

```
1 conv_base.trainable = True
2
3 set_trainable = False
4 for layer in conv_base.layers:
5     if layer.name == 'block5_conv1':
6         set_trainable = True
7     if set_trainable:
8         layer.trainable = True
9     else:
10        layer.trainable = False
```

Listing 5.23. Fine-tuning the model

```
1 model.compile(loss='binary_crossentropy',
2                 optimizer=optimizers.RMSprop(lr=1e-5),
3                 metrics=['acc'])
4
5 history = model.fit_generator(
6     train_generator,
7     steps_per_epoch=100,
8     epochs=100,
9     validation_data=validation_generator,
10    validation_steps=50)
```

5.3.2. Fine-tuning (4)

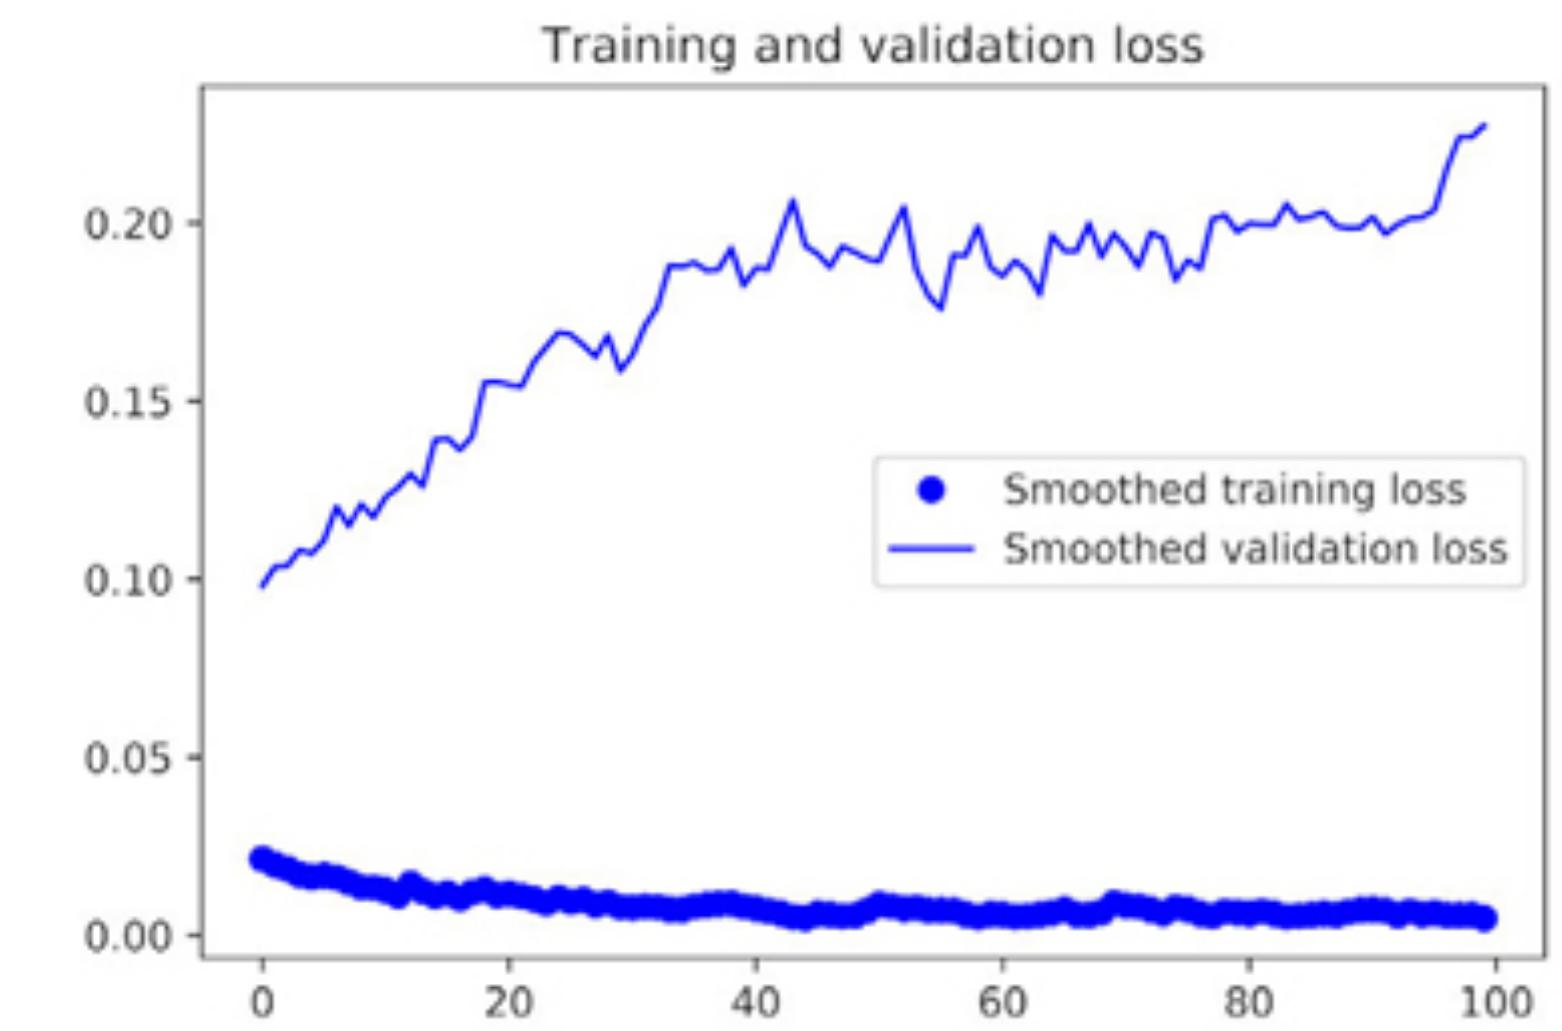

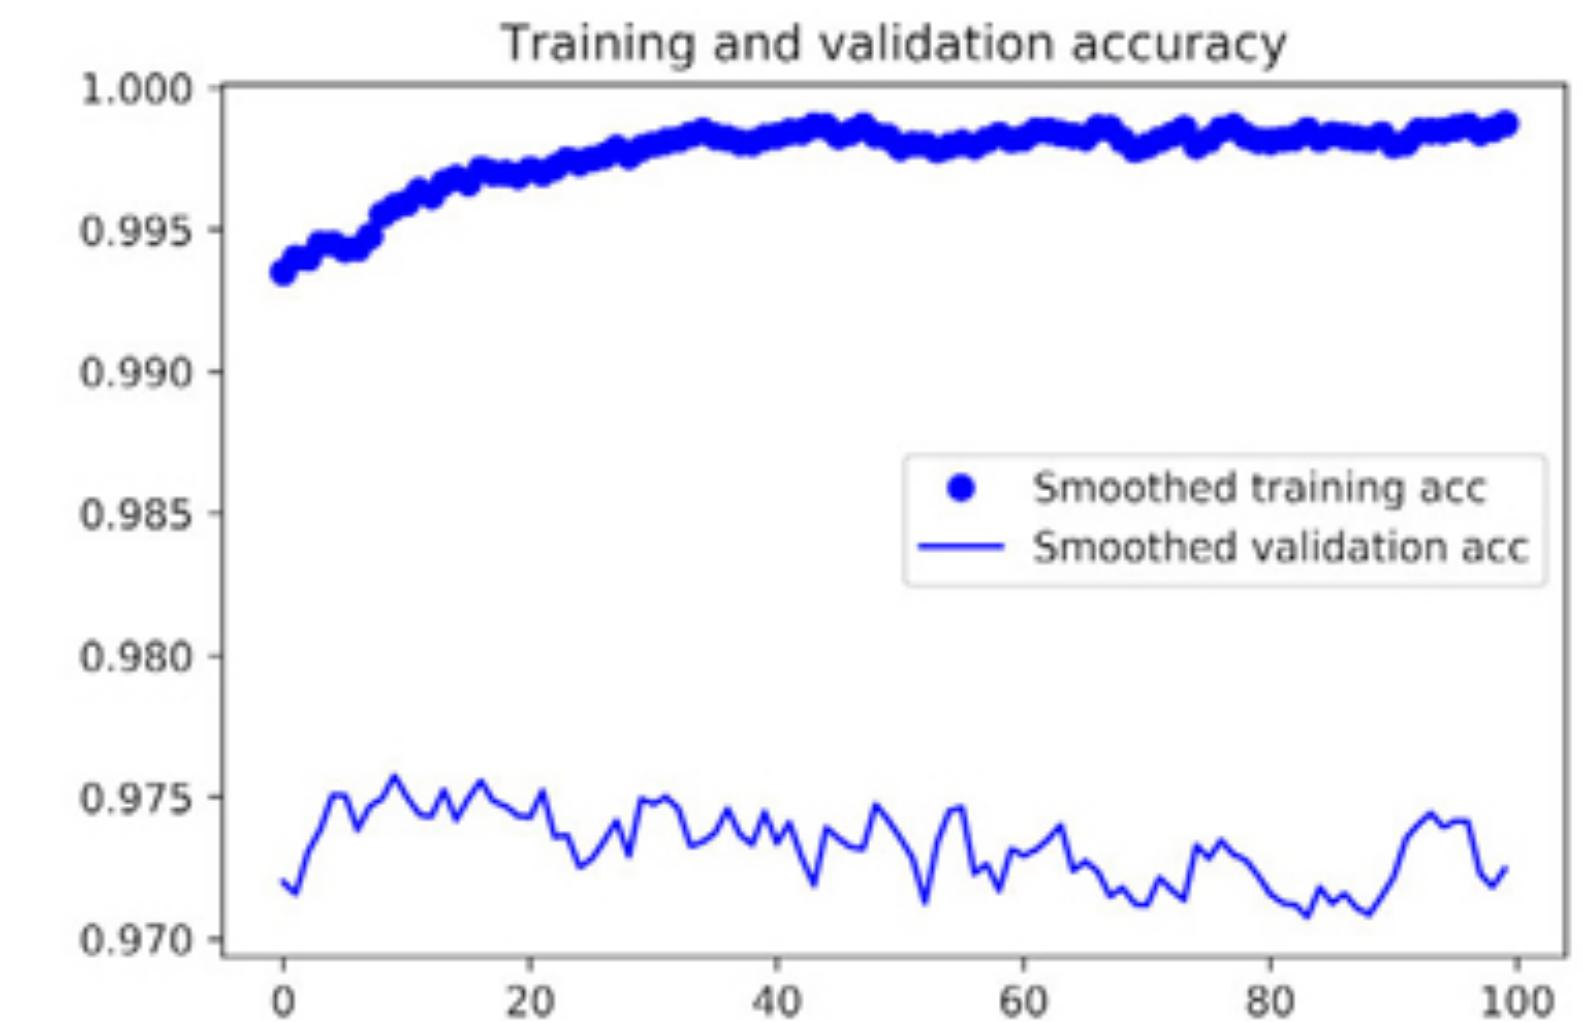

- Plot the results
 - Curves look noisy: smooth them by replacing every loss and accuracy with exponential moving averages of these quantities - see next slide.

5.3.2. Fine-tuning (5)

Listing 5.24. Smoothing the plots

```
1 def smooth_curve(points, factor=0.8):
2     smoothed_points = []
3     for point in points:
4         if smoothed_points:
5             previous = smoothed_points[-1]
6             smoothed_points.append(previous * factor + point * (1 - factor))
7         else:
8             smoothed_points.append(point)
9     return smoothed_points
10
11 plt.plot(epochs,
12           smooth_curve(acc), 'bo', label='Smoothed training acc')
13 plt.plot(epochs,
14           smooth_curve(val_acc), 'b', label='Smoothed validation acc')
15 plt.title('Training and validation accuracy')
16 plt.legend()
17
18 plt.figure()
19
20 plt.plot(epochs,
21           smooth_curve(loss), 'bo', label='Smoothed training loss')
22 plt.plot(epochs,
23           smooth_curve(val_loss), 'b', label='Smoothed validation loss')
24 plt.title('Training and validation loss')
25 plt.legend()
26
27 plt.show()
```

5.3.2. Fine-tuning (6)

```
1 test_generator = test_datagen.flow_from_directory(  
2     test_dir,  
3     target_size=(150, 150),  
4     batch_size=20,  
5     class_mode='binary')  
6  
7 test_loss, test_acc = model.evaluate_generator(test_generator, steps=50)  
8 print('test acc:', test_acc)
```

- The validation accuracy curve look much cleaner. You're seeing a nice 1% absolute improvement in accuracy, from about 96% to above 97%
- Evaluation of the model on the test data show an accuracy of 97%
- This result is better than the winner of the Kaggle competition, **using only 10% av the training data (2' vs. 20')**. This is make possible by modern deep-learning techniques.

5.3.3. Wrapping up

- Convnets are the best type of machine-learning models for computer-vision tasks
- A convnets can be train from scratch even on a very small dataset, with decent results.
 - Small dataset, overfitting, data augmentation
- It's easy to reuse an existing convnet on a new dataset via feature extraction
- Fine-tuning adapts to a new problem some of the representations previously learned by an existing model.

Summary: Chap 5

- Convnets are the best tool for attacking **visual**-classification problems.
- Convnets work by learning a **hierarchy** of modular **patterns and concepts** to represent the visual world.
- The representations they learn are easy to **inspect**—convnets are the opposite of black boxes!
- You’re now capable of training your own convnet from scratch to solve an image-classification problem.
- You understand how to use visual data **augmentation** to fight overfitting.
- You know how to use a **pretrained** convnet to do **feature extraction and fine-tuning**.
- You can generate **visualizations** of the filters learned by your convnets, as well as heatmaps of class activity.
